# **VOLUME 4.5: TRANSMISSION AND DISTRIBUTION ANALYSIS**

#### **HIGHLIGHTS**

KCP&L Greater Missouri Operations Company (GMO) transmission losses as a percent of peak load served are low relative to the SPP footprint as a whole.

SPP identified one economic project in the GMO footprint through its ITP10 process – a voltage conversion of the latan – Stranger Creek 161 kV transmission line to 345 kV. A need date was set at 1/1/2019.

SPP identified one reliability project in the GMO footprint through its ITPNT process – a rebuild of the Harrisonville North – Ralph Green 69 kV line. A need date was set at 6/1/2015.

A total of eight transmission projects have been identified in the GMO territory, with need dates between 2015 and 2033.

PURPOSE: This rule specifies the minimum standards for the scope and level of detail required for transmission and distribution network analysis and reporting.

# SECTION 1: ADEQUACY OF THE TRANSMISSION AND DISTRIBUTION NETWORKS

(1) The electric utility shall describe and document its consideration of the adequacy of the transmission and distribution networks in fulfilling the fundamental planning objective set out in 4 CSR 240-22.010. Each utility shall consider, at a minimum, improvements to the transmission and distribution networks that—

# 1.1 <u>OPPORTUNITIES TO REDUCE TRANSMISSION POWER AND ENERGY LOSSES</u>

(A) Reduce transmission power and energy losses. Opportunities to reduce transmission network losses are among the supply-side resources evaluated pursuant to 4 CSR 240-22.040(3). The utility shall assess the age, condition, and efficiency level of existing transmission and distribution facilities and shall analyze the feasibility and cost-effectiveness of transmission and distribution network loss-reduction measures. This provision shall not be construed to require a detailed line-by-line analysis of the transmission and distribution systems, but is intended to require the utility to identify and analyze opportunities for efficiency improvements in a manner that is consistent with the analysis of other supply-side resource options;

Electrical losses in a transmission line are primarily dependent on the specific characteristics of the line (conductor type, line length, etc.) and the amount of power flowing (I<sup>2</sup>R) on the transmission line. KCP&L Greater Missouri Operations Company (GMO) uses 161kV transmission lines (approximately 800 miles) for the majority of its load serving substations. Most of GMO's existing 161kV transmission lines use a single 795 ACSR conductor per phase on H-frame wood structures. This design provides a normal line rating of 228 Mva and an emergency rating of 259 Mva for summer conditions. For increased transmission capability and lower line losses, GMO Transmission Engineering

recommended using a line design with two, 795 ACSR conductors per phase on H-frame wood or steel structures. This design provides a normal line rating of 456 Mva and an emergency rating of 518 Mva for summer conditions. Adding the additional conductor per phase reduces the line's electrical resistance by half and results in reduced transmission losses. Transmission Engineering estimated the cost to rebuild a single conductor per phase line to a two conductor per phase line at \$832,200 per mile.

In order to "analyze the feasibility and cost-effectiveness of transmission network loss-reduction measures", GMO Transmission Planning staff analyzed the costs and loss reductions associated with rebuilding five of GMO's most heavily loaded 161kV transmission lines. This analysis involved calculating new impedances values for the five transmission lines converted from single 795 conductor to bundled 795 conductors and performing a loadflow analysis to determine the level of loss reduction for the rebuilt lines. Results of this analysis for 2015 summer peak conditions are shown in Table 1, below.

Table 1: Cost Analysis for 161kV Transmission Line Loss Reduction

۸\/ED۸CE	OCT OF LOCA	S DEDITOTI	ON		Φ /IZ\Λ/		¢24.020
AVERAGE COST OF LOSS REDUCTION \$/KW						\$34,828	

The average cost of loss reduction for these five transmission lines is \$34,828/kw. This is approximately fifteen times the average \$/kw construction cost of latan 2. Clearly transmission loss reduction is not cost effective for GMO when compared to the cost of construction for new supply side resources. This is mainly due to the fact that GMO already has a relatively low loss transmission system.

The GMO transmission system is a relatively low loss network due to good line design, concentration of load, and the distribution of its generation resources throughout its service territory. As shown in Table 2, GMO's projected transmission loss as a percent of peak load served for 2015 summer peak load conditions is only 1.5%. The comparative value for the rest of the Southwest Power Pool (SPP) is 2.43%.

#### 1.1.1 <u>DISTRIBUTION SYSTEM OVERVIEW</u>

The GMO planning groups (Supply, Transmission, and Distribution) assimilates a broad set of engineering inputs to determine how the company will invest in improving the respective systems to meet ongoing load growth, system reliability, operational efficiency and asset optimization needs. The Distribution Planning group analyzes data, identifies patterns, develops electrical models representative of the GMO distribution system, and performs studies to understand and prioritize system improvement needs.

For GMO, the suburban areas of the system are where new development of open land requires the build-out of the distribution system. The highest

load growth is seen on the fringe, demanding investments to serve new emerging electrical loads – largely a capacity issue. Circuits must be tied together more effectively to allow for contingency switching and disperse the load across a larger number of circuits, all the while expanding substation breaker positions for these new circuits. Many investments like this have been made in recent years, especially in the Liberty, Lee's Summit, and Blue Springs areas.

The rural areas have the most widespread infrastructure components and have the fewest or most limited emergency ties, where any load manipulation can cause large disturbances to customers' voltage. Distribution Planning carefully examines these systems to assure customer voltages are within tolerance, a process which demands highquality mapping and device load data. With so many widespread components, acquiring data has become one of the greatest challenges in these areas. One specific project initiated to address rural voltage issues is the Adrian 25kV Substation project, in the Belton service territory. To the North, the City of St. Joseph behaves from a planning perspective like a mini version of the Kansas City Metro Area. The overall electrical energy demand remains stable, with pockets of growth and areas of load decline. The growth areas are on the city's east and north fringes, while the inner core is experiencing reoccupation of old abandoned buildings. For Distribution Planning, the 34kV system in St Joseph presents a unique challenge. While suitable for rural sub-transmission or distribution purposes, the 34kV becomes problematic in dense, urban centers like St Joseph. First, limited capacity on the 34kV system needs to be expanded alongside the 12kV distribution, duplicating the effort to grow the system. Second, the reliability suffers when many customers are tied to one 34kV circuit; one incident could cause a wide-spread outages. The Distribution Planning group will, over time, reduce the geographic reach of the 34kV while meeting immediate load and contingency requirements of the distribution system.

The Distribution Planning group is tasked with elevating the highest priority and highest-risk projects to a point where investments are made earlier than those with lower priorities and risk profiles. Many years of constant review have provided the group with a robust set of criteria within which these problems are evaluated, and even today process improvements are being made to further analyze how well to build out the distribution system to assure cost-effectiveness.

Furthermore, the Long-Term Planning component handled by Distribution Planning assures strategic long-term investments are made. Solutions are selected based upon how well they fit into an area-plan, not only the cost-effectiveness for the immediate need. Between the robust planning criteria and the strategic long-term vision, Distribution Planning will continue to construct the distribution system capable of serving tomorrow's needs by making appropriate investments when they are needed.

On the suburban fringe, Distribution Planning plots out growth patterns to identify substation sites well ahead of the need. To the South and East of Lee's Summit, two sites have already been pursued as future substation sites. On the Northern edge of the Metro Area, several substation sites have already been purchased in anticipation of future load growth. Within the 20-year plan, nine separate new substations or substation expansions will accommodate growth as Kansas City sprawls outward. Distribution Planning constantly reviews the build-out of the distribution system on the suburban fringe as development in Kansas City continues this march North, South, and East of the current Metro Area.

In St Joseph, the future vision would remove the capacity-limited 34kV sub-transmission system and replace it with a 161kV-fed system of distribution substations. An improvement to reliability and capacity, this would eliminate a duplicate layer of maintenance, simultaneously shrinking circuit sizes to reduce a customer's exposure to outages and bringing higher-voltage lines into the St Joseph metro area.

The rural areas of the service territory are envisioned to one day have entirely remotely-received load and condition data – a completely automated system. Today, load information is difficult to obtain and costly for field load checks during peak periods. Strategic and timely decisions can better be made with abundant characteristic data for the components being studied. Efforts are underway to systematically bring all rural components up to metro-area data acquisition standards.

As GMO builds toward its own future here in Kansas City, it is the goal of Distribution Planning to assure that every investment optimizes capital spend and balances risk, meets current and future needs, and is built strategically when and where they are needed. Many tools and a great deal of information is processed and analyzed to develop these strategic plans.

#### 1.1.2 ANNUAL SCOPE OF WORK

Throughout each year, Distribution Planning prepares a number of system studies to determine weaknesses or risks to reliability and to assess the overall adequacy of our distribution system. The majority of the work focuses on increasing reliability and prioritizing work based upon cost, scope, impact, and effectiveness. This work is centered around four (4) specific areas which include capacity, contingency, voltage and condition. The table below illustrates the various deliverables associated with each focus area:

**Table 3: Distribution Planning - Annual Scope of Work** 

	Study Name	Deliverable
Category	•	
Capacity	Load Preservation 5 Yr. System Expansion – Load Device Weather Adjustment 20 Year Forecast Circuit Rating Study	Black Start Plan Budgetary Recommendations Distribution Load Book Forecasted Substation Loads Circuit Rating utilized for Operational Guidance
Contingency	5 Yr. System Expansion – contingency N-1 Circuit Contingency Study N-1 Transformer Contingency Study	Budgetary Recommendations Circuit Contingency Plan Transformer Contingency Plan
Voltage & Losses	Phase Balancing Voltage Drop Studies System Efficiency Studies Capacitor Studies Voltage Regulation Studies	Load-Swap Recommendations DVC Operational Guidance System Loss Studies Capacitor Installations Substation Tap Settings
Condition	Worst Performing Circuits Circuit Review Short Circuit Studies Other Reviews	Budgetary Recommendations Budgetary Recommendations Customer-Required Special Studies

To complete this identified scope of work, GMO Planning Engineers utilize a variety of tools that make use of the device loads and system schematics as input. There are several tools currently in use at GMO to collect and process this information.

#### PI/Network Manager

During the summer of 2010, the new Network Manager Energy Management (SCADA) system was placed in-service. With this ABB product GMO also acquired a PI Historian data archive, which now contains device loads and other historical system characteristics. Once all system components are merged into the new system, the PI Historian will be the primary archive for engineers to find and extract load and voltage history. The figure below provides a snapshot of PI Historian.

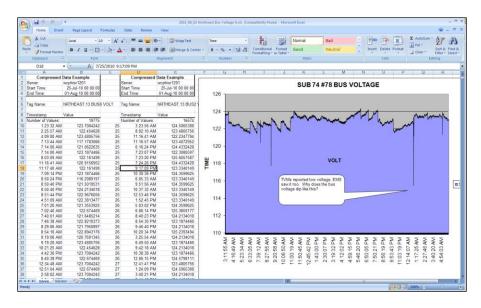

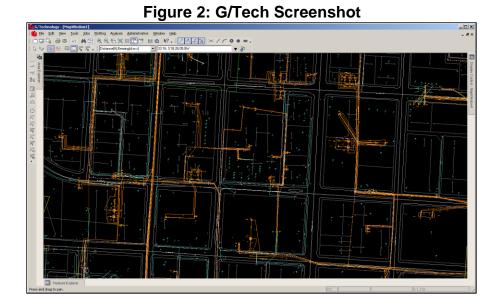

Figure 1: PI Screenshot

#### **GTechnology**

The software mapping tool used by Distribution Planning engineers is called GTech. The GMO distribution system G.I.S. database is viewed and extracted from GTech, where engineers acquire model data for use in SynerGEE. Device characteristics and connectivity drive load-flow models in use by Distribution Planners. The figure below provides a snapshot of G/Tech.

Volume 4.5: Transmission and Distribution Analysis

#### **SynerGEE**

A multipurpose tool primarily used by engineers to analyze load flow characteristics of distribution feeders. Distribution Planning is also responsible for providing fault current information to customer's electrical contractors when performing arc-flash studies, a process which requires the use of SynerGEE. The figure below provides a snapshot of the SyngerGee software program.

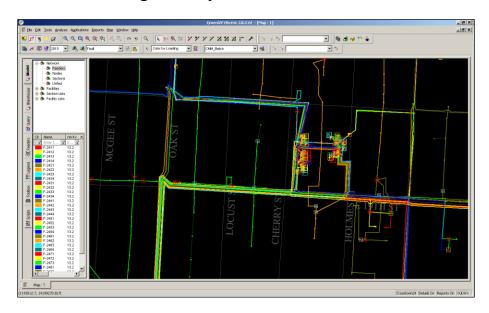

Figure 3: SynerGEE Screenshot

#### 1.1.2.1 Capacity Planning

Device loads, such as substation transformer and distribution circuit loads are collected annually from a number of remote-sensing sources and are weather-adjusted to determine the effects of temperature (heating & cooling). This load data is compared to previous years' loads and device maximum loading to determine how the load is changing over time and if any component is overloaded in need of an upgrade. These types of problems are given a higher priority than others to assure continued reliability.

#### 1.1.2.1.1 <u>Device Weather Adjustment</u>

The whole system improvement process begins with Device Weather Adjustment. There are a number of ways engineering monitors and records the loads experienced across the distribution system, and however this is done, load data is gathered and tabulated. The daily peak demand is then compared with the daily high temperature (for Winter, the daily low temperature), and a comparison is made using an excel scatter-plot with a linear-regression best-fit line.

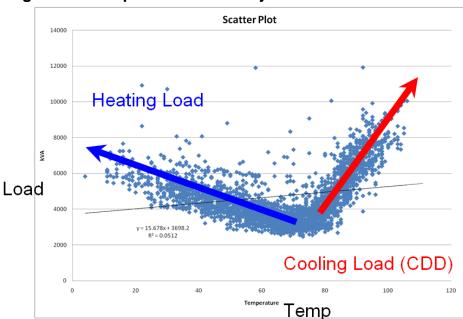

Figure 4: Example of Weather-Adjustment Scatter Plot

Distribution Planning cleanses the data using filters to assure outlying data points (abnormal behaviors) are omitted from the study. What results is a linear equation, where the variable 'x' refers to the temperature. For 'x', Distribution Planning inserts 100 degrees Fahrenheit, the chosen planning temperature at GMO. This then yields a weather-adjusted peak demand, which is utilized throughout the rest of the planning process.

Figure 5: Example Scatter Plot after data filtered to show collating loads

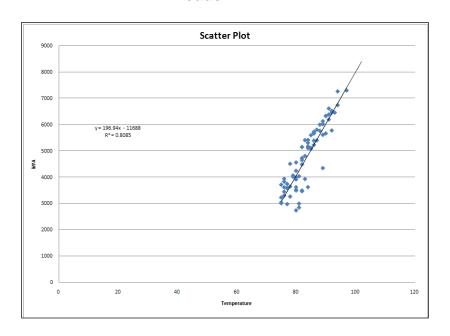

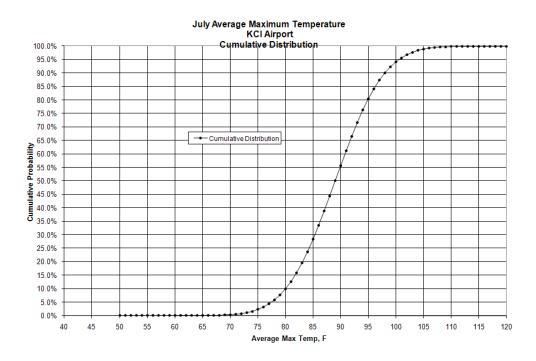

Figure 6: Cumulitive Distribution Plot - 95% certainty at 100 degrees

For load driven higher by increasing temperatures, the chart above shows at what temperature the Kansas City Area tops out.

Temperatures above 105 degrees Fahrenheit are almost nonexistent historically and statistically. For Kansas City, the 95% mark (5% of the time temperature runs hotter) is 100 degrees F.

For Distribution Planning, taking 5% risk means planning to a weather-adjusted temperature of 100 degrees F.

One hundred degrees Fahrenheit planning temperature was chosen for several reasons. First, Corporate Planning uses 100 degrees for their studies, and Distribution Planning felt it appropriate to match their criteria for distribution expansion projects. Second, 100 degrees represents a five percent risk, meaning there is a five percent chance in any given year the temperature will exceed 100 degrees on at least one day, sending system loads beyond designed capacity. Third, 100 degrees best-matched the previous design criteria in terms of system improvement dollars needed in a given year.

#### 1.1.2.1.2 <u>Circuit Rating Study</u>

Armed with weather-adjusted loads, Distribution Planning can produce ratings for each circuit. Again, this study is done in several different ways depending on the configuration and style of the distribution components being looked at. The most complex of these studies deals with underground feeder cables within duct bank, which de-rate each other by mutual heating. Whatever the case may be, Distribution Planning uses weather-adjusted loads to determine capacity 'choke-points' in order to rate the circuit. These ratings are provided to operations to set alarms, and become an integral part of the N-1 Contingency Study. These ratings are also compared with native device loads to determine where normal-load

capacity expansions are needed, leading to budget recommendations.

## 1.1.2.1.3 <u>Spatial Electric Load Forecast Study (Electric Vehicle Study)</u>

GMO Planning Engineers have been able to leverage the information gathered through a study KCP&L completed with the help of Integral Analytics, Inc. (IA) conducted a rigorous electric vehicle impact study and a long-range spatial load forecast study. The study details long-range substation load growth due to increases in employment, population, and estimates the future adoption of electric vehicles at different penetration levels for the entire KCP&L service territory. The study intent was to help distribution planners identify future capacity constrained areas due to future electric vehicle load additions and to proactively plan for distribution expansion work before system loading became an issue. The results of this study are representative of the entire KCP&L service area, including much of the GMO service area, and will be utilized for both.

Electric vehicles present a significantly large end use load to the distribution system. To study the potential distribution impact of vehicle electrification, one must understand the customer key drivers of adoption. Therefore, IA designed a discrete choice survey and recruited 113 KCP&L residential customers randomly to participate in a discrete choice survey online. The survey results were processed and unique electric vehicle adoption and charging behavior segments were developed. The segmentation was applied to the KCP&L customer base with demographic information pulled from the Experian database. A probability of adoption score was assigned to each KCP&L customer based on the segmentation analysis. The scoring identified the customers most likely to purchase electric vehicles. Finally, the customers were mapped geographically to locate potential electric vehicle customer clusters at different penetration levels in the KCP&L service territory.

The worst case scenario of 100 percent of new vehicles sold in the KCP&L service territory are electric vehicles show, on average, the load will increase by 2,500 kilowatts per substation over the next 20 years. Therefore, residential electric vehicle charging at the local or neighborhood levels will resemble normal load growth. KCP&L annually reviews distribution feeder capabilities and implements necessary upgrades to meet the electricity requirements. KCP&L does not anticipate substation loading issues. However, KCP&L does anticipate localized loading issues at the distribution line transformer level providing service to a cluster of customer who all adopt EV. Localized distribution line transformer loading can be easily resolved by upgrading the size of the transformer.

The electric vehicle impact study provides distribution planning a 20 year forecast of future loading by substation for different electric vehicle penetration scenarios. The scenario based planning

methodology has allowed distribution planning to understand the impact of electric vehicles in the KCP&L service territory at the substation level. The electric vehicle study did highlight a few potential loading issues but overall the impact of electric vehicles on the distribution networks will be very minimal over the next 20 years. Appendix 4.5.A contains a complete copy of the "Spatial Electric Load Forecast Study".

#### 1.1.2.2 Contingency Planning

Contingency Planning is similar to Capacity Planning in its view of loads compared to device capacity, but deals in an N-1 contingency setting. GMO designs its system to withstand a failure of any one component at a given time. It is the responsibility of Distribution Planning Engineers to determine system weaknesses which do not comply with this and to make the necessary changes to allow emergency switching to restore power without overloading backup devices. These issues have a secondary priority in the budgetary process.

#### 1.1.2.2.1 <u>N-1 Contingency</u>

The annual contingency study will provide the earliest indication of system improvement needs. It is more likely wire upgrades will be needed in the case of feeder or transformer loss, rather than there being simply too much native load on a single feeder or substation transformer. For Distribution Planning, the N-1 Contingency Study is a very systematic and complex process due to the magnitude of the individual distribution system circuit components. Distribution Planners break apart circuits into segments of load, and establish switching orders for restoration in the case of a feeder or substation transformer loss. SynerGEE, using G.I.S. models exported from GTech and weather-adjusted load data, actually determines how

that load is spread across the circuit by taking a third input from the C.I.S. – metered customer load data. The SynerGEE CMM Module allows Distribution Planning to allocate feeder breaker weather-adjusted load on a given feeder based upon how it appears by its metered customer load, which is typically measured in kWh.

Three very complex inputs into one N-1 Contingency Study using a highly-technical software program yields effective results determining where system improvement is needed. By using the model to rearrange the configuration of circuitry using SynerGEE, Distribution Planning can detect where mapping errors exist, where low voltage can be problematic, and where wire sizes can limit how the distribution system is operated. Contingency Planning is an intensely complex process taking significant engineering time in order to determine system weaknesses for a given planning year. The study is completed every year for every distribution feeder and for the loss of every substation transformer.

These weaknesses, once identified, are further analyzed to determine with impact to system reliability and are ranked against each other correspondingly. Ultimately, this ranking, energy efficiency impacts, reliability and customer impact risks, and the project cost determine whether a system improvement is constructed or not. Distribution Planning therefore must not only identify the weakness, but provide some budgetary estimation and project description. It also becomes the responsibility of Distribution Planning to thoroughly communicate why a project exists throughout the company, until it becomes part of the approved budget and is handed-off to a design engineer for sponsorship.

#### 1.1.2.3 Distribution Voltage

At the customer-end of any given line, distribution voltage must be maintained within specific tolerances. It is the responsibility of Distribution Planning to assure system-level issues do not adversely affect the voltage received by GMO customers. To do this, G.I.S. models are used in a load-flow program called SynerGEE to simulate voltage levels in the field. In addition to supplying adequate voltage levels to our customers, we strive to maintain an efficient low-loss distribution system. Several examples of this are the annual load balancing efforts and capacitor studies to optimize voltage levels and reduce system losses.

#### 1.1.2.3.1 Loss Studies

Another method of analyzing overall system efficiency is through the performance of system loss studies. These are done periodically and the information gathered is used by Planning Engineering as well as in rate case filings. The most recent system loss study was performed by Siemens in October, 2014. A complete copy of this study, "GMO Electric System Loss Analysis", can be found in Appendix 4.5.B.

#### 1.1.2.3.2 KCP&L Green Circuits Analysis

Another example of GMO's efforts to improve overall circuit efficiency and reduce system losses was to utilize a recent study commissioned by KCP&L and completed by EPRI (Electric Power Research Institute). This study analyzed various loss reduction options such as phase balancing, capacitor controls, reconductoring, and/or voltage optimization. The information gathered by this study has been used by Planning Engineering to optimize their approach to circuit construction, configuration and operation for both KCP&L and GMO service areas. A complete

copy of this study, "KCP&L Green Circuits Analysis Study", can be found in Appendix 4.5.C.

#### 1.1.2.3.3 <u>Transformer Efficiency Analysis</u>

Currently, GMO purchases transformers based on the Total Ownership Cost (TOC), which includes the transformer purchase price as well as the cost of the no-load and load-losses associated with each transformer, capitalized over a 30 year expected transformer life. Since 2010, all GMO transformers were purchased utilizing the Department of Energy (DOE) transformer efficiency standards, which has enabled GMO to optimize the TOC of all transformers over a 30 year period.

#### 1.1.2.4 Condition

Another important focus area for Planning Engineering deals with component conditions and their effect on reliability as it relates to capacity, contingency, voltage and overall system efficiency.

Ongoing strategic planning to maintain reliability must account for device degradation over time, and planning engineers look for cost-effective replacement or maintenance opportunities where they coincide with capacity expansion plans. By working with the Asset Management group to determine the best course of action, these replacements in some cases are combined into Distribution Planning's capacity expansion projects – an increase in project scope from the normal course of action. System expansion to replace degraded system components can be a more cost-effective solution than the "run-to-failure" strategy.

#### 1.1.2.4.1 <u>URD Cable Replacement Programs</u>

Currently, there are two cable replacement programs in existence at GMO: 1) Proactive Cable Replacement, and 2) Reactive Cable Replacement.

The proactive cable replacement program uses a mix of analysis techniques. One technique does partial discharge testing of entire underground loops and replaces the cable sections that do not pass this test. Another option is to look at the number of failures on the loop and calculate the number of segments that have had failures. If this percentage is greater than 40%, the cable segments on the entire loop are eligible for replacement. These methods provide targeted proactive cable replacements based on cable condition or failure history. The goal is to target high-risk cables, and replace these cable segments before failure.

The reactive cable replacement program requires replacement of a cable when it has failed two or more times. The current policy of the reactive URD replacement program is to replace any direct buried cable after its second failure with cable in conduit. A section of cable receives a priority which is a function of the number of customers affected by the cable outage, the duration of the outage, the vintage of the cable, the number of failures of cable, the time elapsed from the most recent failure, and the number of outages that the lateral has experienced in past 12-months.

#### 1.1.2.4.2 <u>Cable Injection Program</u>

In addition to cable replacement, cable injection proactively addresses high-risk cables. Cable injection techniques prolong the cable's life and improve reliability. Injection can be performed on cables that have faulted, but as with proactive replacement, the goal is to prevent failures from happening in the first place. Injection contractors provide a minimum warranty of 20 years, with the option to upgrade to as much as 40 years with better injection fluids. Cable injection companies are used by GMO to perform these activities.

#### 1.1.2.4.3 Worst Performing Circuit Analysis

The inventory assessment projects that have been completed in the past have given GMO an advantage that we can employ with worst performing circuit analysis. GMO identify worst performing circuits from Missouri requirements criteria and develop reliability plans and make repairs. The performance of circuits varies significantly and no two of them have identical problems to fix. We use the assessment data to be included in our analysis of those worst performing circuits. There are approximately 70 to 80 WPC's under

review each year that covers Missouri and Kansas's regulatory rules.

#### 1.1.2.4.4 Pole Replacement and Reinforcement Program

The Distribution Pole Replacement/Reinforcement Program addresses reliability issues associated with the condition of distribution poles. GMO annually conducts a ground-line inspection of the system to determine if there is a need to replace or reinforce distribution poles. The evaluation includes an examination for indications of decay and/or fungi at or below ground level, hollowness and shell rot. When a pole is identified for replacement or reinforcement, the Company uses an independent contractor who is an expert in pole evaluation, maintenance, and repair, to prioritize and coordinate pole maintenance or replacement. The work is prioritized based on conditions with the greatest risk to safety and impact to customer reliability. Annual pole rejection rate is calculated to be 0.0356% per 1,000 pole inspections.

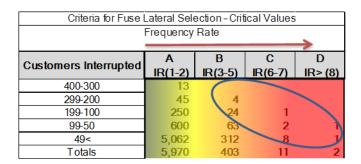

#### 1.1.2.4.5 Lateral Improvement Program

This program is an organized effort to evaluate the performance of all laterals on our system. The criteria considered for fuse lateral selection are customer interrupted and outage frequency.

Examples shown in Figure 8 below are all laterals to consider for analytical reviews to determine critical value. The blue circle drawn around the areas with the highest critical values is the chosen laterals. Laterals tagged as critical value represents 0.9% of the total. Figure 8 show customers interrupted ranges starting at 400 customers interrupted (CI) down to less than 49 CI per event.

Frequency rate is identified by using letters starting with (A), (B), (C), and (D). Each letter category represents 25% of the total frequency rate equal to 100%. The numbers within the figure are lateral counts in each category. For instance, IR (1-2) means one or two outage events occurring on a lateral. The selection scheme has proven to be the best approach.

Figure 8

### 1.1.2.4.6 <u>Mobile Substations</u>

Asset Management is also looking into the purchase of 2 mobile substation units to reduce the risk of long-term power outages in the event of a failure of a high-voltage substation transformer. Presently, there is a need for several units with various capacities and voltage levels in addition to the mobile units KCP&L and KCP&L GMO currently have in their fleet. Purchase of these additional units will provide greater operational flexibility while also minimizing spare transformer inventory throughout KCP&L's service areas.

### 1.2 ASSESSMENT OF INTERCONNECTING NEW FACILITIES

(B) Interconnect new generation facilities. The utility shall assess the need to construct transmission facilities to interconnect any new generation pursuant to 4 CSR 240-22.040(3) and shall reflect those transmission facilities in the cost benefit analyses of the resource options;

GMO Transmission Planning must meet interconnection needs of transmission customers for connection to and use of the GMO transmission system. The Interconnection procedures are covered within the Federal Energy Regulatory Commission (FERC) approved transmission tariff provisions where customers are provided detailed transmission studies and interconnection estimates for connecting to and using GMO's transmission system.

An example of such is the 2014 review of potential sites for addition of new KCP&L generation resources that considered large additions (620 MW combined cycle units), medium size additions (200 MW simple cycle units), and small incremental additions (100 MW reciprocating engine units). This process included review of brown field (existing) and green field (new) sites within or near the KCP&L and GMO service territories. GMO 161 kV transmission lines are generally not adequate to provide firm transmission for a 620 MW generation resource unless multiple (2+) transmission lines are available for generation outlet. GMO 345 kV transmission lines can generally provide firm transmission for a 620 MW generation resource if there is available transmission capacity.

The resource siting study identified potential sites for addition of large, mid, and small generation resources. Transmission Planning provided a range of transmission costs for each site and identified potential transmission limitations.

Any GMO generation resource addition that would impact transmission level (>60 kV) flows would have to proceed through the SPP Generation Interconnection process before it could be interconnected to the transmission system. The resource addition would also have to be included in the SPP Aggregate Facility Study process to obtain firm transmission service for delivery of generation to load.

## 1.3 <u>ASSESSMENT OF TRANSMISSION UPGRADES FOR POWER PURCHASES</u>

(C) Facilitate power purchases or sales. The utility shall assess the transmission upgrades needed to purchase or sell pursuant to 4 CSR 240-22.040(3). An estimate of the portion of costs of these upgrades that are allocated to the utility shall be reflected in the analysis of preliminary supply-side candidate resource options; and

GMO is member of the Southwest Power Pool (SPP) a Regional Transmission Organization (RTO), mandated by the Federal Energy Regulatory Commission to ensure reliable supplies of power, adequate transmission infrastructure, and competitive wholesale prices of electricity. As a North American Electric Reliability Corporation (NERC) Regional Entity, SPP oversees enforcement and development of reliability standards. SPP has members in nine states. As a member of SPP, GMO participates in the regional transmission expansion plan processes of the RTO. Two recent expansion plan processes conducted by SPP are the Balanced Portfolio (June 2009) and the Priority Projects (April 2010).

The Balanced Portfolio is an SPP strategic initiative to develop a grouping of economic based regional transmission upgrades that benefit the SPP region while allocating the cost of those upgrades regionally. Projects in the Balanced Portfolio include transmission upgrades of 345 kV projects that will provide customers with potential savings that exceed project costs. These economic upgrades are intended to reduce congestion on

the SPP transmission system, resulting in savings in generation production costs. Economic upgrades may provide other benefits to the power grid; i.e., increasing reliability and lowering required reserve margins, deferring reliability upgrades, and providing environmental benefits due to more efficient operation of assets and greater utilization of renewable resources. SPP analyzed the benefits and costs of the Balanced Portfolio and established that these projects provided a region-wide per-customer average benefit of \$1.66/month with a corresponding cost of \$0.88/month. The Balanced Portfolio included a total of seven transmission projects with an estimated engineering and construction cost of approximately \$700 million (initial estimate). Two of these projects are within the KCP&L service territory near the GMO service territory. They are the latan-Nashua 345 kV line (~\$54 million) and the Swissvale-Stilwell tap at West Gardner (~\$2 million).

In the Priority Projects plan, SPP sought to identify, evaluate, and recommend transmission projects that will improve the SPP transmission system and benefit the region, specifically projects that would improve regional production costs, reduce grid congestion, enable large-scale renewable resources (primarily wind), improve the Generation Interconnection and Aggregate Facility Study processes, and better integrate SPP's east and west regions. A total of six transmission projects with an estimated cost of \$1.1 billion were selected for construction in the Priority Projects process providing a variety of benefits to the region. One of the projects included is the Nebraska City-Mullin Creek-Sibley 345 kV transmission line. These Priority Projects achieve the strategic goals of reducing transmission congestion, improving the Aggregate Facility Study process by creating additional transfer capability and increasing the ability to transfer power in an eastward direction for the majority of the transmission paths between SPP's western and eastern areas.

The costs for the Balanced Portfolio and Priority Projects will be allocated on a regional basis by specific allocation methods whether or not GMO makes any resource additions. For this reason, GMO's share of the allocated costs for Balanced Portfolio and Priority Projects were not reflected in the analysis of preliminary supply-side candidate resource options.

The preferred resource plan for GMO includes gas fired combustion turbines, additional wind and solar generation resources. The solar resources are relatively small amounts of generation and are assumed to be interconnected at the distribution voltage levels. For this reason there is no associated transmission interconnection or upgrade costs for these solar generation resources. The wind resources remotely located in western Kansas will utilize regional transmission capacity and transmission service to deliver their output to GMO loads. The combustion turbine resources are assumed to be located at the Sibley power plant after retirement of the existing smaller coal fired units (1 & 2) there. With retirement of the those units and expansion of the Sibley 345kV substation as part of the SPP Priority Projects there should be adequate transmission capacity at the Sibley site to deliver the output of new generation resources to GMO loads. The only transmission investment needed for the new generation resources at Sibley would be any upgrades needed for generation interconnection to the existing substation. Any new generation resources would have to apply for interconnection through the SPP generator interconnection process and apply for transmission service in the SPP Aggregate Study process.

# 1.4 ASSESSMENT OF TRANSMISSION OR DISTRIBUTION IMPROVEMENTS WITH RESPECT TO COST EFFECTIVENESS OF DSM OR SUPPLY-SIDE RESOURCES

(D) Incorporate advanced transmission and distribution network technologies affecting supply-side resources or demand-side resources.

The utility shall assess transmission and distribution improvements that may become available during the planning horizon that facilitate or expand the availability and cost effectiveness of demand-side resources or supply-side resources. The costs and capabilities of these advanced transmission and distribution technologies shall be reflected in the analyses of each resource option.

### 1.4.1 CAPACITOR AUTOMATION EFFORTS

Since the early 1990's, KCP&L has worked with Sensus (formerly Telemetric) to develop automated capacitor controls with integrated radios for use throughout the KCP&L service territory. This technology uses radios that leverage the commercial cell coverage infrastructure while also providing secure communications and technology applications for KCP&L users. This added technology is particularly cost effective and successful in areas where other communication infrastructure is not cost effective. Due to the experience in the legacy KCP&L territory, KCP&L has been able to quickly deploy automated capacitors in GMO areas following the Aquila (GMO) acquisition.

In anticipation of retirement of the CellNet fixed network system (in legacy KCP&L) due to it's replacement with a new AMI mesh network, KCP&L has contracted with Sensus to pilot their Flexnet communications system. Flexnet utilizes cellular radio technology, but on a private cellular network rather than commercial cellular coverage. The original target for Flexnet will be to replace the Cellnet communications in legacy KCP&L through the second half of 2015. KCP&L/GMO will evaluate the Flexnet pilot to determine if it can be economically expanded for greater coverage, including into the GMO territory.

The business case for automated capacitors includes:

Upgrade existing capacitors with controls with new technical features

Voltage Override

**Neutral Sensing** 

Limiting number of switching operations per day

Ability to change setpoints remotely

Ability to obtain power quality data for improved customer service

Optimizing utilization of these existing capacitor banks

Enhancing safety for KCP&L/GMO workers

Five minute time delay in control for a close after an open

One minute timer for close after faceplate control operation

Reduced O&M

Limiting number of capacitor patrols due to real time data

Limiting number of customer voltage complaints

Extending life of existing capacitor switches

Improved Distribution and Transmission Power Factor

Enhance System Stability

Enhance system volt/VAr response

Increase system efficiency

# SECTION 2: AVOIDED TRANSMISSION AND DISTRIBUTION COST

(2) Avoided Transmission and Distribution Cost. The utility shall develop, describe, and document an avoided transmission capacity cost and an avoided distribution capacity cost. The avoided transmission and distribution capacity costs are components of the avoided demand cost pursuant to 4 CSR 240-22.050(5)(A).

The GMO transmission projects included in the SPP regional planning processes for reliability improvement or economic benefits would not be impacted by the implementation of DSM programs. Therefore, the only avoided cost for transmission facilities are the transmission equipment additions associated with distribution facility expansions.

### 2.1 <u>IMPACT OF DSM ON DISTRIBUTION EXPANSION</u>

As in the 2012 IRP submittal, KCP&L GMO made assumptions regarding planned system expansion projects in areas that are designated as "growth areas" versus areas designated as "established areas". Again, targeting was focused on capital projects associated within established areas since targeted DSM programs were unlikely to be able to delay the need to expand substations on the fringe of metro-area growth due to the fact that these areas contained significant "green space" with large areas that remain undeveloped.

Distribution Planning's annual review of 20 year load projections revealed the fact that loads for these "established areas" continue to flatten and more commonly, decline, which has eliminated the need for expansion projects in these areas. It seems reasonable that as load growth has fallen off in the established areas, that efficiencies gained by replacing older heating/cooling units, lighting, and other older appliances, would begin to significantly impact peak loads for these areas.

With the exception of the St. Joseph Downtown area, GMO generally lacks the type of urban core found within the downtown KC area. This limits the number of substations that can be categorized as being located in "established areas". Combined with relatively modest to flat load growth, and in some cases declining loads, GMO substations located with established areas do not offer the same opportunity for targeted DSM efforts. The relatively few areas that are established either have sufficient capacity available to absorb current growth rates, or are in load decline. These areas will continue to be monitored by Distribution Planning to determine if future opportunities for targeted DSM might become available. Should economic conditions improve, and/or significant redevelopment occurs in these established areas, it seems reasonable that there may be sufficient opportunities to target DSM to avoid/eliminate the cost to expand substation capacities for these areas.

# SECTION 3: ANALYSIS OF TRANSMISSION NETWORK PERTAINENT TO A RESOURCE ACQUISITION STRATEGY

(3) Transmission Analysis. The utility shall compile information and perform analyses of the transmission networks pertinent to the selection of a resource acquisition strategy. The utility and the Regional Transmission Organization (RTO) to which it belongs both participate in the process for planning transmission upgrades.

### 3.1 TRANSMISSION ASSESSMENTS

(A) The utility shall provide, and describe and document, its-

### 3.1.1 TRANSMISSION ASSESSMENT FOR CONGESTION UPGRADES

1. Assessment of the cost and timing of transmission upgrades to reduce congestion and/or losses, to interconnect generation, to facilitate power purchases and sales, and to otherwise maintain a viable transmission network;

In 2009, the SPP Board of Directors approved a new Integrated Transmission Planning (ITP) process that will determine the transmission needed to maintain electric reliability and provide near- and long-term economic benefits to the SPP RTO region, which includes all or parts of Arkansas, Kansas, Louisiana, Missouri, Nebraska, New Mexico, Oklahoma, and Texas. Successful implementation of the ITP will result in a list of transmission expansion projects and completion dates that facilitate the creation of a reliable, robust, flexible, and cost-effective transmission network that improves access to the region's diverse resources, including its vast potential for renewable energy. Significant wind energy development is taking place in parts of Oklahoma, Kansas, Nebraska, and Texas.

The ITP is an iterative three-year process that includes a 20-Year, 10-Year, and Near-Term Assessment. The 20-Year Assessment evaluates the high voltage

transmission (345 kV +) needs over a 20 year study period to meet load growth and other future scenarios and potential developments. The second iteration of the 20-Year Assessment (ITP20), conducted in 2012-2013, included an examination of high voltage transmission needs while taking into account reliability, economic, and public policy needs. Five distinct futures were considered to account for possible variations in system conditions over the assessment's 20-year horizon, including: (1) business as usual; (2) additional wind assuming a 20% federal Renewable Electricity Standard; (3) additional wind as in item (2) plus approximately 10 GW of additional wind generation to be exported outside of SPP; (4) combined policy, which approximates the effects of additional investment in Demand Side Management and Smart Grid technology, additional wind as in item (2), and a carbon constraint; and (5) a joint SPP/MISO future. The SPP Board of Directors voted to approve the ITP20 Report on July 30, 2013. The cost of the plan was estimated at \$560 million through the construction of 405 miles of 345 kV lines, 31 miles of 161 kV lines, and six various 345 kV step-down transformers. Two projects were identified in the GMO area – reconductoring the Clinton – Truman – N. Warsaw 161 kV line and a new Mullin Creek 345/161 kV transformer.

The 10-Year Assessment is a value-based planning approach that analyzes the transmission system over a 10-year horizon. Economic and reliability analyses are utilized to identify 100 kV and above solutions for issues identified on the 69 kV and above system, as well as issues identified by the 20-Year Assessment appropriate for the 10-Year Assessment. The second iteration of the 10-Year Assessment (ITP10) was conducted in 2013-2014, with the final report issued in January 2015. Two distinct futures were considered to account for possible variations in system conditions: (1) business-as-usual, which includes all statutory/regulatory renewable mandates and goals resulting in 11.5 GW of renewable resources modeled in SPP, load growth projected by load serving entities, and SPP member-identified generator retirement projections, and (2) decreased base load capacity, which considers factors that could drive a reduction in existing generation. The recommended 2015 ITP10 portfolio was

estimated at \$273 million engineering and construction cost and includes projects needed to meet potential reliability, economic, and policy requirements. These projects, with a total estimated net present value revenue requirement of \$334 million, are expected to provide net benefits of approximately \$1.4 billion over the life of the projects under a business-as-usual scenario containing 10.3 GW of wind capacity expected to be contracted by SPP members. Project need dates were identified between 2019 and 2024. GMO received one project as a result of the ITP10 study – a voltage conversion of the current latan – Stranger Creek 161 kV line to 345 kV. SPP identified the need date for this upgrade as 1/1/2019.

The Near-Term Assessment of the ITP evaluates transmission system reliability in the near-term planning horizon. The Assessment will identify potential problems using NERC Reliability Standards, SPP Criteria, and local planning criteria. Mitigation plans are developed to meet regional reliability needs and identify necessary reliability upgrades for all voltage levels for approval and construction. The most recent iteration of the Near-Term Assessment (ITPNT) was conducted in 2014, with the final report issued in January 2015. The 2015 ITPNT used two scenario models built across multiple years and seasons to account for various system conditions across the near-term horizon. The first scenario contains projected transmission transfers between SPP legacy BAs and generation dispatch on the system. The second scenario maximized all applicable confirmed long-term firm transmission service with its necessary generation dispatch. Additionally, a Consolidated Balancing Authority (CBA) model scenario was built across the same years and seasons to show the needs on the SPP transmission system as a result of a Security Constrained Unit Commitment (SCUC) and Security Constrained Economic Dispatch (SCED). SPP performed reliability analyses identifying potential bulk power system problems. These findings were presented to Transmission Owners and stakeholders to solicit transmission solutions. Also considered were transmission options from other SPP studies, such as the Aggregate Study and Generation Interconnection processes. From the resulting list of potential solutions, staff identified the best regional solutions for potential reliability violations. Staff

presented these solutions for member and stakeholder review at SPP's December 2014 planning summit. Through this process, SPP developed a final list of 69 kV and above solutions necessary to ensure the reliability in the SPP region in the near-term. Engineering and Construction (E&C) cost estimates for new and modified reliability projects needed in the years 2015-2020 totaled \$248.2 million. GMO had one project identified – a rebuild of the Harrisonville North – Ralph Green 69 kV line. SPP identified the need date for this upgrade as 6/1/2015.

The ITP process has been a fundamental change in the way in which transmission planning occurs at the SPP region. This process, with its iterative nature and wide range of planning periods, helps to ensure robust planning, lowest cost solutions and a reliable bulk electric grid for the region. It also strengthens the balance between future needs of the system with an everchanging grid topology, load growth, generation resources, energy policy and planning criteria.

### 3.1.2 TRANSMISSION ASSESSMENT FOR ADVANCE TECHNOLOGIES

# 2. Assessment of transmission upgrades to incorporate advanced technologies;

GMO currently make use of four advanced technologies in its transmission system; Real Time Line Rating, Hybrid Structure Design, Solid Dielectric Cables, and Fiber Optic Shield Wire.

GMO currently uses a commercial application, based upon actual conductor tension, to provide real time line ratings for two 161 kV transmission lines. Basing the ratings upon a direct measurement of the actual conductor tension is the most direct method currently available to establish real time (dynamic) conductor ratings, and using the conductor tension captures all of the local conditions that affect the conductor tension and current carrying capacity. The real time line ratings are provided not only to our Transmission System Operators

but also to the SPP Reliability Coordinator. This equipment allows transmission lines to carry more power when conditions are favorable and reduce transmission congestion.

GMO uses a hybrid steel and wood H-Frame structures for both single and double circuit applications. Using steel poles, provides easier installation due to their lower weights compared to other materials, and the use of wood x-bracing provides a cost effective option to conventional steel bracing and allows us to use established stock materials. Steel replacement arms and bracing for both 161 and 345 kV H-Frame structures are used to reduce construction and maintenance costs. Each assembly is rated for helicopter installation weight not to exceed 800 pounds per lift. This layout allows the use of smaller helicopters for both energized and normal maintenance change out work.

GMO is using solid dielectric cables at 69 kV for specific applications at power plants where limited space made conventional bus or overhead circuit installations impractical or impossible.

GMO currently uses optical ground wire (OPGW) for most or all of new shield wire installations. This gives not only superior lightning performance, due to the lower resistance of the OPGW compared to conventional galvanized steel strand shield wires, but also provides a high capacity path for internal communications and system protection functions. The standard OPGW options provide either 48 or 72 single mode fibers per shield wire.

### 3.1.3 AVOIDED TRANSMISSION COST ESTIMATE

# 3. Estimate of avoided transmission costs;22.045 Transmission and Distribution Analysis,

The GMO transmission projects included in the SPP regional planning processes for reliability improvement or economic benefits would not be impacted by the implementation of DSM programs. Therefore, the only avoided cost for

transmission facilities are the transmission equipment additions associated with distribution facility expansions.

### 3.1.4 REGIONAL TRANSMISSION UPGRADE ESTIMATE

4. Estimate of the portion and amount of costs of proposed regional transmission upgrades that would be allocated to the utility, and if such costs may differ due to plans for the construction of facilities by an affiliate of the utility instead of the utility itself, then an estimate, by upgrade, of this cost difference;

Table 4 below shows the SPP projected annual transmission revenue requirement allocated to GMO for regional transmission upgrades.

**Table 4: SPP Projected ATRR Allocated to GMO** 

h	
YEAR	ANNUAL TRANSMISSION REVENUE REQUIREMENT ALLOCATED TO GMO
1 = / \(\)	TREGOTTEMENT ALLOCATED TO GIVE
2015	\$ 14,508,513
2016	\$ 15,753,698
2017	\$ 18,674,538
2018	\$ 22,983,256
2019	\$ 24,807,737
2020	\$ 25,009,083
2021	\$ 25,694,263
2022	\$ 26,520,867
2023	\$ 28,766,403
2024	\$ 27,885,705
2025	\$ 27,005,007

On April 4, 2012 Great Plains Energy ("GXP"), the holding company for both KCP&L and GMO, and American Electric Power ("AEP") announced the formation of a company to build and invest in transmission infrastructure. The new company, Transource EnergySM LLC ("Transource"), will pursue competitive transmission projects in the SPP region, the MISO and PJM regions, and potentially other regions in the future. GXP owns 13.5 percent of Transource

through its newly-formed subsidiary, GPE Transmission Holding Company, LLC ("GPETHCO"). AEP owns the other 86.5 percent of Transource through its subsidiary, AEP Transmission Holding Company, LLC ("AEPTHC").

At this point, it is GXP's intent to pursue, develop, construct, and own through GPETHCO's interest in Transource – rather than through KCP&L and/or GMO – any future regional and inter-regional transmission projects subject to regional cost allocation. While it is premature to determine the specific impact on the regionally allocated costs resulting from constructing projects within Transource, it is anticipated that the partnership between GXP and AEP will provide for a financially-strong, cost-competitive, and technically-proficient transmission development entity. The scale, execution experience, and engineering expertise that Transource expects to be able to bring to the projects should provide benefits to customers through lower construction costs, better access to capital, and operational efficiencies.

### 3.1.5 REVENUE CREDITS ESTIMATE

# 5. Estimate of any revenue credits the utility will receive in the future for previously built or planned regional transmission upgrades; and

Estimated Transmission Service revenue that GMO will receive is based on the amounts included in FERC account 456100. Table 5 below shows historical and projected amounts for account 456100 for 2012-2025. The revenue credit process for future regional transmission upgrades has not been fully developed by SPP at this time and is not included in these projections.

**Table 5: GMO Transmission Service Revenues from SPP** 

YEAR	TS REVENUE	BASIS
2012	\$6,567,610	actual
2013	\$7,962,443	actual
2014	\$10,379,426	forecast
2015	\$9,087,716	budget
2016	\$9,087,716	projected
2017	\$9,087,716	projected
2018	\$9,087,716	projected
2019	\$9,087,716	projected
2020	\$9,087,716	projected
2021	\$9,087,716	projected
2022	\$9,087,716	projected
2023	\$9,087,716	projected
2024	\$9,087,716	projected
2025	\$9,087,716	projected

### 3.1.6 TIMING OF NEEDED RESOURCES ESTIMATE

6. Estimate of the timing of needed transmission and distribution resources and any transmission resources being planned by the RTO primarily for economic reasons that may impact the alternative resource plans of the utility.

The SPP Priority Projects of regional transmission projects included one project in the GMO service territory. The Nebraska City-Mullin Creek-Sibley 345 kV line

is a primarily economic-based transmission project. The expected in-service date for Nebraska City-Mullin Creek-Sibley 345 kV line is 6/1/2017. It will provide additional opportunity to expand the development of renewal resources in the northwest part of Missouri.

The 2015 ITP10 identified one economic project in the GMO service territory – a voltage conversion of the current latan – Stranger Creek 161 kV line to 345 kV. The need date for this project was identified as 1/1/2019. It will have minimal impact on GMO alternative resource plans.

These projects were identified within the SPP transmission planning process to reduce transmission congestion and provide regional production costs and trade benefits.

### 3.2 USE OF RTO TRANSMISSION EXPANSION PLAN

(B) The utility may use the RTO transmission expansion plan in its consideration of the factors set out in subsection (3)(A) if all of the following conditions are satisfied:

See response to Section 3.1.1 above for description of SPP RTO transmission expansion planning processes.

### 3.2.1 <u>UTILITY PARTICIPATION IN RTO TRANSMISSION PLAN</u>

# 1. The utility actively participates in the development of the RTO transmission plan;

GMO actively participates in the development of SPP transmission expansion plans through a number of related activities. These include participation in the Model Development Working Group (MDWG), the Transmission Working Group (TWG), and regional transmission expansion workshops

Participation in the MDWG involves reviewing and updating the transmission planning models used for regional transmission expansion analysis. This

includes adding GMO transmission projects into the planning models and providing a substation level load forecast for the seasonal and future years planning models. The expected generation dispatch required to meet GMO load requirements is also included in these models. These models form the basis for the reliability analysis needed to identify future transmission projects to maintain reliable service and reduce transmission congestion.

The Transmission Working Group (TWG) is responsible for planning criteria to evaluate transmission additions, seasonal Available Transfer Capability (ATC) calculations, seasonal flowgate ratings, oversight of coordinated planning efforts, and oversight of transmission contingency evaluations. The TWG works with individual transmission owners on issues of coordinated planning and North American Electric Reliability Corporation (NERC) and SPP compliance. The TWG coordinates the calculation of the ATC for commerce maintaining regional reliability, while ensuring study procedures and criteria are updated to meet the regional needs of SPP, in cooperation with governing regulatory entities. The TWG is responsible for publication of seasonal and future reliability assessment studies on the transmission system of the SPP region. The TWG works closely with the Economic Studies Working Group (ESWG) to develop the scope documents used to direct the analysis and studies performed for the ITP process.

SPP hosts three to four ITP workshops annually to get stakeholder input to the transmission planning process and provide analysis results for stakeholder review. The workshops allow SPP stakeholders to provide input on assumptions for economic analysis review identified needs and proposed solutions selected by SPP. GMO proposes projects through SPP's FERC Order No. 1000 process, reviews selected transmission projects in its area and coordinates with SPP regarding details within its area that may affect proposed solutions. In other instances GMO offers an operating guide to mitigate a transmission problem and avoid new transmission construction.

### 3.2.2 ANNUAL REVIEW OF RTO EXPANSION PLANS

2. The utility reviews the RTO transmission overall expansion plans each year to assess whether the RTO transmission expansion plans, in the judgment of the utility decision makers, are in the interests of the utility's Missouri customers;

GMO reviews transmission projects in its area coordinates with SPP regarding details within its area that may affect proposed solutions or requests restudy for projects that it believes are not required. GMO planning personnel participate throughout the year within the planning process providing insight and review of the transmission plans. In some instances GMO may be able to offer an operating guide to mitigate a transmission problem and avoid or delay new transmission construction. Also, GMO personnel participate in the overall approval of RTO expansion plans through the SPP approval process within the Markets and Operation Policy Committee and Members Committee.

### 3.2.3 ANNUAL REVIEW OF SERVICE TERRITORY EXPANSION PLAN

3. The utility reviews the portion of RTO transmission expansion plans each year within its service territory to assess whether the RTO transmission expansion plans pertaining to projects that are partially- or fully-driven by economic considerations (i.e., projects that are not solely or primarily based on reliability considerations), in the judgment of the utility decision-makers, are in the interests of the utility's Missouri customers;

GMO reviews transmission plans and projects within its service territory that develop through the SPP RTO transmission expansion plan. Many are zonal projects providing additional obligations to serve or meet specific planning and bulk electric reliability criteria.

For region-wide project sets such as the SPP Balanced Portfolio projects meet a wide range of needs including reduced production costs, reduced congestion, reduced system losses and base reliability needs. For example, in the case of

the latan-Nashua 345kV project in KCP&L's territory, it is a project that will significantly reduce congestion of a major regional flowgate near the Kansas City-north area and directly relieves growing limitations on the ability to dispatch KCP&L's latan 2 generating unit. The latan – Nashua project provides approximately 8 Mw of loss reduction for KCP&L and GMO systems at peak load conditions. Iatan – Nashua also eliminates two flowgates; one on the KCP&L – Westar boundary and one on the GMO – KCP&L boundary.

The SPP Priority Projects of regional transmission projects included one project in the GMO service territory. The Nebraska City-Mullin Creek-Sibley 345 kV line is a primarily economic-based transmission project. This project was identified within the SPP transmission planning process to reduce transmission congestion and provide regional production costs and trade benefits. It will provide additional opportunity to expand the development of renewal resources in the northwest part of Missouri. This project should also eliminate the Cooper South flowgate which has exhibited significant transmission congestion for north to south energy transfers.

## 3.2.4 <u>DOCUMENTATION AND DESCRIPTION OF ANNUAL REVIEW OF RTO OVERALL AND UTILITY-SPECIFIC EXPANSION PLANS</u>

4. The utility documents and describes its review and assessment of the RTO overall and utility-specific transmission expansion plans; and

GMO reviews transmission projects in its area and coordinates with SPP regarding details within its area that may affect proposed solutions. In other instances GMO may be able to offer an operating guide to mitigate a transmission problem and avoid new transmission construction.

### 3.2.5 AFFILIATE BUILD TRANSMISSION PROJECT DISCUSSION

5. If any affiliate of the utility intends to build transmission within the utility's service territory where the project(s) are partially- or fully-driven by economic considerations, then the utility shall explain why such affiliate

built transmission is in the best interest of the utility's Missouri customers and describe and document the analysis performed by the utility to determine whether such affiliate-built transmission is in the interest of the utility's Missouri customers.

On April 4, 2012 Great Plains Energy ("GXP"), the holding company for both KCP&L and GMO, and American Electric Power ("AEP") announced the formation of a company to build and invest in transmission infrastructure. The new company, Transource EnergySM LLC ("Transource"), will pursue competitive transmission projects in the SPP region, the MISO and PJM regions, and potentially other regions in the future. GXP owns 13.5 percent of Transource through its newly-formed subsidiary, GPE Transmission Holding Company, LLC ("GPETHCO"). AEP owns the other 86.5 percent of Transource through its subsidiary, AEP Transmission Holding Company, LLC ("AEPTHC").

At this point, it is GXP's intent to pursue, develop, construct, and own through GPETHCO's interest in Transource – rather than through KCP&L and/or GMO – any future regional and inter-regional transmission projects subject to regional cost allocation. While it is premature to determine the specific impact on the regionally allocated costs resulting from constructing projects within Transource, it is anticipated that the partnership between GXP and AEP will provide for a financially-strong, cost-competitive, and technically-proficient transmission development entity. The scale, execution experience, and engineering expertise that Transource expects to be able to bring to the projects should provide benefits to customers through lower construction costs, better access to capital, and operational efficiencies.

### 3.3 RTO EXPANSION PLAN INFORMATION

(C) The utility shall provide copies of the RTO expansion plans, its assessment of the plans, and any supplemental information developed by the utility to fulfill the requirements in subsection (3)(B) of this rule.

The following SPP regional transmission planning reports are provided as attachments to this report.

```
2009 Balanced Portfolio - Final Approved Report.pdf (Appendix 4.5 - 3.3A)

Priority Projects Phase II Rev 1 Report - 4-27-10_final.pdf (Appendix 4.5 - 3.3B)

20130730_2013_ITP20_Report_clean.pdf (Appendix 4.5 - 3.3C)

Final_2015_ITP10_Report_BOD_Approved_012715 .pdf (Appendix 4.5 - 3.3D)

Final_2015_ITPNT_Assessment_BOD_Approved.pdf (Appendix 4.5 - 3.3E)

2015_STEP_Report.pdf (Appendix 4.5 - 3.3F)

2015_STEP_Project_List_Protected (Appendix 4.5 - 3.3G)
```

The Balanced Portfolio and Priority Projects reports are described in Section 1.3 above. The ITP20, ITP10, ITPNT reports are described in Section 3.1.1 above. The 2015 SPP Transmission Expansion Plan (STEP) Report and Project List summarize 2014 activities that impact future development of the SPP transmission grid. Seven distinct areas of transmission planning are discussed in this report, each of which are critical to meeting mandates of either the 2011 SPP Strategic Plan or the nine planning principles in FERC Order 890. These areas are Transmission Services, Generation Interconnection, Integrated Transmission Planning, Balanced Portfolio, High Priority Studies, Sponsored Upgrades, and Interregional Coordination.

### 3.4 TRANSMISSION UPGRADES REPORT

(D) The utility shall provide a report for consideration in 4 CSR 240-22.040(3) that identifies the physical transmission upgrades needed to interconnect generation, facilitate power purchases and sales, and otherwise maintain a viable transmission network, including:

## 3.4.1 TRANSMISSION UPGRADES REPORT – PHYSICAL INTERCONNECTION WITHIN RTO

1. A list of the transmission upgrades needed to physically interconnect a generation source within the RTO footprint;

It is not possible to provide a specific list of transmission upgrades needed to physically interconnect a generation resource within the SPP footprint. Any generation interconnection request within the SPP must proceed through the generation interconnection process as defined by the SPP transmission tariff. That process will examine the specific location proposed for generator interconnection and develop the necessary transmission upgrades needed at that location.

Generally speaking, generator interconnections for green field sites will require a three breaker ring bus substation for interconnection to the existing transmission system. Estimated costs for the interconnecting substation are in the range of \$8-10 million at 345kV and \$4-8 million at 161kV. Costs for interconnection of new generation resources at existing substations are generally significantly less due to the availability of existing substation infrastructure.

### 3.4.2 TRANSMISSION UPGRADES REPORT – DELIVERABILITY ENHANCEMENT WITHIN RTO

2. A list of the transmission upgrades needed to enhance deliverability from a point of delivery within the RTO including requirements for firm transmission service from the point of delivery to the utility's load and

# requirements for financial transmission rights from a point of delivery within the RTO to the utility's load;

In the SPP, requests for firm transmission service are processed through the Aggregate Facility Study (AFS) process. The AFS process is performed three times per year by collectively analyzing specific transmission service requests, including those associated with generation interconnection reguests, across the entire SPP footprint. These service reservations are modeled based on control area to control area transfers. The transmission system is assessed with these potential service requests and, where needed, transmission improvements are identified that would enable the service to occur without standard or criteria violations. All transmission customers are allocated cost responsibility for portions of the various upgrades needed to deliver all of the transmission service requests. Transmission customers may decline to pay their portion of the allocated cost and drop out of the study process. Study analysis is repeated on the reduced set of transmission service requests. This is an iterative process until a final set of transmission service requests for those customers remaining in the process has been reached. The remaining transmission customers with service requests in the process agree to the projects needed to deliver the remaining transmission service and share the resulting upgrade costs. Those remaining upgrade projects are included in the next SPP transmission expansion plan process.

Because of the iterative nature of the Aggregate Facility Study process it is not possible to identify specific transmission upgrades needed to deliver energy from a resource in the RTO footprint to GMO until the process for a specific transmission service request has been completed.

# 3.4.3 TRANSMISSION UPGRADES REPORT – PHYSICAL INTERCONNECTION OUTSIDE RTO

3. A list of transmission upgrades needed to physically interconnect a generation source located outside the RTO footprint;

It is not possible to develop a list of specific upgrades needed to interconnect a generation resource located outside the SPP without actually making a generation interconnection request at a specific location.

### 3.4.4 TRANSMISSION UPGRADES REPORT – DELIVERABILITY ENHANCEMENT OUTSIDE RTO

4. A list of the transmission upgrades needed to enhance deliverability from a generator located outside the RTO including requirements for firm transmission service to a point of delivery within the RTO footprint and requirements for financial transmission rights to a point of delivery within the RTO footprint;

It is not possible to develop a list of specific upgrades needed to deliver capacity and energy from a generation resource located outside the SPP without actually making a generation interconnection request and an associated transmission service request at a specific location.

### 3.4.5 TRANSMISSION UPGRADES REPORT – ESTIMATE OF TOTAL COST

5. The estimated total cost of each transmission upgrade; and

A list of GMO transmission projects included in the 2015 SPP Transmission Expansion Plan (STEP) is shown below in Table 6.

**Table 6: GMO Transmission Upgrades 2015 SPP STEP** 

TRANSMISSION PROJECT	COST ESTIMATE	TYPE	DATE
Build new 31 mile 345kV line from latan – Nashua.	\$51,647,155	Balanced Portfolio	06/01/15
Rebuild of Harrisonville North - Ralph Green 69kV line.	\$4,329,248	ITP	06/01/15
Build new 105 mile 345kV line Sibley to new Mullin Creek (formerly Maryville) substation. Upgrade Sibley substation with the necessary breakers and terminal equipment.	\$241,448,558	high priority	06/01/17
Build new 345kV substation at Mullin Creek (formerly Maryville) & new 65 mile 345kV from the Mullin Creek substation to the Missouri/Nebraska state border towards OPPD's Nebraska City substation.	\$90,750,965	high priority	06/01/17
Reconductor 3.21 miles from Blue Springs South to Prairie Lee 161kV for 2000 amp	\$3,039,096	ITP	06/01/18
Reconductor 2.5 miles Blue Springs South - Blue Springs East 161kV for 2000 amp	\$2,399,248	ITP	06/01/18
latan – Stranger Creek 345 kV Voltage Conversion	\$16,119,446	ITP	01/01/19
Install new 345/161 kV transformer at Mullin Creek (formerly Maryville).	\$12,600,000	ITP	01/01/33

Total estimated construction cost for these transmission upgrades is \$422,333,716.

### 3.4.6 TRANSMISSION UPGRADES REPORT - COST ESTIMATES

# 6. The estimated fraction of the total cost and amount of each transmission upgrade allocated to the utility.

A list of GMO transmission projects included in the 2015 SPP STEP and the portion of their estimated cost allocated to GMO is shown below in Table 7.

**Table 7: Transmission Upgrade Cost Allocated to GMO** 

Table 1. Transillission opgrade Co	ot 7 modatod to	<u> </u>	
	COST	% ALLOCATED	
TRANSMISSION PROJECT	ESTIMATE	TO GMO	GMO\$
Build new 31 mile 345kV line from latan – Nashua.	\$51,647,155	TBD	TBD
Rebuild of Harrisonville North - Ralph Green 69kV line.	\$4,329,248	100	\$4,329,248
Build new 105 mile 345kV line Sibley to new Mullin Creek (formerly Maryville) substation. Upgrade Sibley substation with the necessary breakers and terminal equipment.	\$241,448,558	4.2	\$10,140,839
Build new 345kV substation at Mullin Creek (formerly Maryville) & new 65 mile 345kV line from the Mullin Creek substation to the Missouri/Nebraska state border towards OPPD's Nebraska City substation.	\$90,750,965	4.2	\$3,811,541
Reconductor 3.21 miles from Blue Springs South to Prairie Lee 161kV for 2000 amp	\$3,039,096	68.4	\$2,078,741
Reconductor 2.5 miles Blue Springs South - Blue Springs East 161kV for 2000 amp	\$2,399,248	68.4	\$1,641,086
latan – Stranger Creek 345 kV Voltage Conversion	\$16,119,446	4.2	\$677,017
Install new 345/161 kV transformer at Mullin Creek (formerly Maryville).	\$12,600,000	68.4	\$8,618,400

The cost allocation between SPP members for Balanced Portfolio projects has not been determined at this time. A primary feature of the Balanced Portfolio cost allocation is to provide all SPP members a benefit/cost ratio of at least 1.0 and thus there will be revenue transfers in order to keep members at or above that threshold.

#### SECTION 4: ADVANCED TECHNOLOGY ANALYSIS

(4) Analysis Required for Transmission and Distribution Network Investments to Incorporate Advanced Technologies.

## 4.1 TRANSMISSION UPGRADES FOR ADVANCED TRANSMISSION TECHNOLOGIES

(A) The utility shall develop, and describe and document, plans for transmission upgrades to incorporate advanced transmission technologies as necessary to optimize the investment in the advanced technologies for transmission facilities owned by the utility. The utility may use the RTO transmission expansion plan in its consideration of advanced transmission technologies if all of the conditions in paragraphs (3)(B)1. Through (3)(B)3. are satisfied.

KCP&L/GMO will use advanced technologies such as Hybrid Structure Design, Solid Dielectric Cables, and Fiber Optic Shield Wire where applicable in transmission upgrades included in the SPP regional transmission expansion plan.

### 4.2 <u>DISTRIBUTION UPGRADES FOR ADVANCED DISTRIBUTION</u> TECHNOLOGIES

(B) The utility shall develop, and describe and document, plans for distribution network upgrades as necessary to optimize its investment in advanced distribution technologies.

GMO has not established a program to invest in distribution network upgrades to optimize it's investments in advanced distribution technologies. Instead, GMO deploys advanced distribution technologies selectively to the network where they are the most economical alternative to maintain the desired level of operational performance, reliability, and power quality.

The previous discussion, in Section 1.4 of this document, discusses how GMO plans distribution network upgrades, many of which incorporate the deployment of previously established advanced grid technologies.

### 4.3 OPTIMIZATION OF INVESTMENT IN ADVANCED TRANSMISSION AND DISTRIBUTION TECHNOLOGIES

(C) The utility shall describe and document its optimization of investment in advanced transmission and distribution technologies based on an analysis of—

### 4.3.1 OPTIMIZATION OF INVESTMENT – TOTAL COSTS AND BENEFITS

1. Total costs and benefits, including:

### 4.3.1.1 <u>Distribution Analysis</u>

GMO has not yet performed a comprehensive analysis to optimize investments in advanced distribution technologies pursuant to 4 CSR 240-22.045(4)(C).

KCP&L developed a DRAFT SmartGrid Vision, Architecture, and Road Map in 2008 as a potential guide to future KCP&L and GMO investments in advanced distribution technologies. The road map focused on the deployment of the advanced distribution technologies needed to implement the SmartGrid functions as described in Title XIII of the Energy Independence and Security Act of 2007 (EISA).

With the passage of the American Recovery and Reinvestment Act of 2009 (ARRA) in February 2009, it became apparent that the draft road map would be too aggressive and possibly limiting from a technical point of view. The architecture, on which the plan was developed, was based on prior EPRI Intelligrid research. It was unclear, to what extent, the NIST SmartGrid Interoperability Framework initiative funded by ARRA may

change our future SmartGrid architecture design and technology selections.

With technology architecture uncertainties and an overly aggressive schedule of the ARRA funded SmartGrid Investment Grants (3 years), KCP&L/GMO management decided to focus on pursuing a DOE SmartGrid Demonstration Grant. KCP&L was awarded this grant in 2009 and executed a contract with the DOE for the demonstration in September 2010. The project will end in the first half of 2015.

Upon completion of the SmartGrid Demonstration Project KCP&L/GMO plans to use the findings of the project to enlighten KCP&L's technology vision, architecture, and road map that will provide the framework for evaluating feasibility of these and similar advanced technologies.

KCP&L/GMO will perform a studies to optimize investments in advanced distribution that incorporates cost-benefit analysis to determine if a business case can be made for technology deployment. Learning from the SmartGrid Demonstration will be used in these analyses when appropriate.

## 4.3.2 <u>OPTIMIZATION OF INVESTMENT - COST OF ADVANCED GRID INVESTMENTS</u>

### A. Costs of the advanced grid investments;

### 4.3.2.1 Distribution

Refer to comments in Section 4.3.1.1

# 4.3.3 OPTIMIZATION OF INVESTMENT - COST OF NON-ADVANCED GRID INVESTMENTS

#### B. Costs of the non-advanced grid investments;

### 4.3.3.1 Distribution

### 4.3.4 <u>OPTIMIZATION OF INVESTMENT – REDUCTION OF RESOURCE</u> <u>COSTS</u>

C. Reduced resource costs through enhanced demand response resources and enhanced integration of customer-owned generation resources; and

### 4.3.4.1 Distribution

Refer to comments in Section 4.3.1.1

### 4.3.5 OPTIMIZATION OF INVESTMENT - REDUCTION OF SUPPLY-SIDE COSTS

D. Reduced supply-side production costs;

### 4.3.5.1 <u>Distribution</u>

Refer to comments in Section 4.3.1.1

### 4.4 <u>COST EFFECTIVENESS OF INVESTMENT IN ADVANCED</u> TRANSMISSION AND DISTRIBUTION TECHNOLOGIES

2. Cost effectiveness, including

### 4.4.1 <u>COST EFFECTIVENESS – INCREMENTAL COSTS ADVANCED GRID TECHNOLOGIES VS NON-ADVANCED GRID TECHNOLOGIES</u>

A. The monetary values of all incremental costs of the energy resources and delivery system based on advanced grid technologies relative to the costs of the energy resources and delivery system based on non-advanced grid technologies;

#### 4.4.1.1 Distribution

Refer to comments in Section 4.3.1.1

### 4.4.2 <u>COST EFFECTIVENESS – INCREMENTAL BENEFITS ADVANCED</u> GRID TECHNOLOGIES VS NON-ADVANCED GRID TECHNOLOGIES

B. The monetary values of all incremental benefits of the energy resources and delivery system based on advanced grid technologies relative to the costs and benefits of the energy resources and delivery system based on non-advanced grid technologies; and

### 4.4.2.1 <u>Distribution</u>

Refer to comments in Section 4.3.1.1

### 4.4.3 OPTIMIZATION OF INVESTMENT - NON-MONETARY FACTORS

C. Additional non-monetary factors considered by the utility;

### 4.4.3.1 Distribution

Refer to comments in Section 4.3.1.1

#### 4.4.4 OPTIMIZATION OF INVESTMENT – SOCIETAL BENEFIT

3. Societal benefit, including:

### 4.4.4.1 Societal Benefit – Consumer Choice

#### A. More consumer power choices;

### 4.4.4.1.1 <u>Distribution</u>

Refer to comments in Section 4.3.1.1

### 4.4.4.2 <u>Societal Benefit – Existing Resource Improvement</u>

### B. Improved utilization of existing resources;

#### 4.4.4.2.1 Distribution

Refer to comments in Section 4.3.1.1

### 4.4.4.3 Societal Benefit - Price Signal Cost Reduction

C. Opportunity to reduce cost in response to price signals;

### 4.4.4.3.1 Distribution

Refer to comments in Section 4.3.1.1

### 4.4.4.4 Societal Benefit -

D. Opportunity to reduce environmental impact in response to environmental signals; Environmental Impact

### 4.4.4.1 <u>Distribution</u>

Refer to comments in Section 4.3.1.1

### 4.4.5 <u>OPTIMIZATION OF INVESTMENT – OTHER UTILITY-IDENTIFIED</u> FACTORS

4. Any other factors identified by the utility; and

### 4.4.5.1.1 Distribution

Refer to comments in Section 4.3.1.1

### 4.4.6 <u>OPTIMIZATION OF INVESTMENT –OTHER NON-UTILITY IDENTIFIED</u> <u>FACTORS</u>

5. Any other factors identified in the special contemporary issues process pursuant to 4 CSR 240-22.080(4) or the stakeholder group process pursuant to 4 CSR 240-22.080(5).

#### 4.4.6.1.1 Distribution

Refer to comments in Section 4.3.1.1

### 4.5 NON-ADVANCED TRANSMISSION AND DISTRIBUTION INCLUSION

(D) Before the utility includes non-advanced transmission and distribution grid technologies in its triennial compliance filing or annual update filing, the utility shall—

## 4.5.1 NON-ADVANCED TRANSMISSION AND DISTRIBUTION REQUIRED ANALYSIS

1. Conduct an analysis which demonstrates that investment in each non-advanced transmission and distribution upgrade is more beneficial to consumers than an investment in the equivalent upgrade incorporating advanced grid technologies. The utility may rely on a generic analysis as long as it verifies its applicability; and

### 4.5.1.1 Distribution

GMO is not proposing any new non-advanced distribution grid technologies or programs in this triennial IRP compliance filing.

GMO understands that prior to including new non-advanced distribution grid technologies in future IRP filings, GMO will conduct, describe, and document an analysis which demonstrates that investment in each non-advanced distribution upgrade is more beneficial to consumers than an investment in the equivalent upgrade incorporating advanced grid technologies. GMO further understands that we may present a generic analysis as long as we verify its applicability;

## 4.5.2 NON-ADVANCED TRANSMISSION AND DISTRIBUTION ANALYSIS DOCUMENTATION

2. Describe and document the analysis.

#### 4.5.2.1 Distribution

Refer to comments in Section 4.5.1.1

### 4.6 <u>ADVANCED TRANSMISSION AND DISTRIBUTION REQUIRED COST-BENEFIT ANALYSIS</u>

(E) The utility shall develop, describe, and document the utility's cost benefit analysis and implementation of advanced grid technologies to include:

### 4.6.1.1 Distribution

GMO is not proposing any new advanced distribution grid technologies or programs in this triennial IRP compliance filing.

GMO understands that prior to including new advanced distribution grid technology in future IRP filings, GMO will develop, describe, and document the cost benefit analysis for implementation of the advanced grid technology.

Upon completion of the SmartGrid Demonstration Project, GMO plans to use the findings of the project to enlighten GMO's technology vision, architecture, and road map that will provide framework for evaluating the feasibility of and guiding the implementation of advanced distribution grid technologies.

In developing the road map, GMO will use the build and impact metrics from our project and other industry sources to perform a cost/benefit analysis of advanced distribution grid technologies considered prior to implementation.

### 4.6.2 <u>ADVANCED GRID TECHNOLOGIES UTILITY'S EFFORTS</u> <u>DESCRIPTION</u>

1. A description of the utility's efforts at incorporating advanced grid technologies into its transmission and distribution networks;

### 4.6.2.1 Distribution

<u>Historical Advanced Grid Technology Deployments</u>

The distribution grid in place at GMO today is substantially "smart" having benefited from decades of power engineering expertise. The existing systems already execute a variety of sophisticated system operations and protection functions. In addition it should be noted that what is now termed "smart grid" has been under development by GMO and the industry for many years. Much of the automation has been accomplished through incremental applications of technology. The following sections describe many of the advanced distribution technologies that have and are currently being implemented at KCP&L/GMO.

### KCP&L SmartGrid Demonstration Project

KCP&L's SmartGrid Demonstration Project deployed an end-to-end SmartGrid (within Kansas City, MO) that includes a wide array of SmartGrid technologies and components. These have been grouped into five (5) major sectors: Smart Distribution, Smart Metering, Interoperability and Security, Smart End-Use and Smart Generation. Below are additional details within each of these sectors:

#### Smart Distribution

- Distribution Management System (DMS) including
   Outage Management System (OMS) and Distribution
   SCADA
- IP/RF 2 –way Field Area Network for communications
- Advanced distribution applications
- Smart Substation

### Smart Metering

- Advanced Metering Infrastructure (AMI)
- Meter Data Management system (MDM)
- Integration between Customer Info System (CIS),
   MDM, AMI and OMS
- Data Analytics
- Interoperability and Security
  - Enterprise Service Bus (ESB) flexible architecture
  - IEC 61850 Substation Communications

- OpenADR Communications for Advanced Demand Response
- Zigbee Smart Energy Profile (SEP) communications between meters and in-home devices
- State of the art network and physical security

#### Smart End-Use

- Home Energy Management Portal (HEMP)
- Home Area Network (HAN)
- In-Home Display (IHD)
- Time of Use (TOU) pilot rate
- Electric Vehicle (EV) charging

#### Smart Generation

- Distributed Energy Resource Management (DERM) system
- Demand Response (DR) programs
- Utility-owned rooftop solar generation
- Utility scale battery

One of the main goals of the demonstration project was to implement this wide array of technologies and systems and demonstrate the level to which they could be integrated and truly interoperable according to emerging governmental/industry standards. The back office IT integration

and infrastructure components were a very significant part of the overall project. The high number of vendors involved and immaturity (and interpretability) of the industry standards proved challenging to the interpretability objective.

- 4.6.3 KCP&L/GMO PLANS TO USE FINDINGS OF THE SMARTGRID DEMONSTRATION PROJECT TO ENLIGHTEN KCP&L'S TECHNOLOGY VISION, ARCHITECTURE, AND ROAD MAP THAT WILL PROVIDE FRAMEWORK FOR EVALUATING THE FEASIBILITY OF, AND GUIDING THE IMPLEMENTATION OF ADVANCED DISTRIBUTION GRID TECHNOLOGIES.DISTRIBUTION ADVANCED GRID TECHNOLOGIES IMPACT DESCRIPTION
- 2. A description of the impact of the implementation of distribution advanced grid technologies on the selection of a resource acquisition strategy; and

The implementation of (or lack thereof) distribution advanced grid technologies did not influence the selection of the resource acquisition strategy presented in this filing.

The advanced distribution grid technologies being evaluated through KCP&L's SmartGrid Demonstration Project, are foundational, potentially enabling technologies that may provide traditional operational benefits to the utility (including GMO) while enabling new demand side management and pricing programs; integration of utility and customer owned distributed generation; greater grid utilization through increased monitoring and control of grid resources; and enhanced utilization of customer demand response capabilities.

GMO anticipates that the results of SmartGrid Demonstration Project and subsequent benefit cost analyses will determine that several of the advanced distribution grid technologies will be determined to be cost effective, or at a minimum we will understand under what conditions they become cost effective.

As a DOE Smart Grid Demonstration Project requirement, KCP&L produced its first and second Interim Technology Performance Reports (TPR) on December

31, 2012 and December 31, 2013 respectively. These documents summarized all achievements on the project through the respective dates. Key topics include summaries of the project design, implementation, testing, analysis, and some lessons learned. Due to the voluminous size of these reports, they have not been included in the Annual Update, but can be downloaded from the following DOE website;

https://www.smartgrid.gov/recovery\_act/program\_impacts/regional\_demon\_stration\_technology\_performance\_reports

A third Interim Technology Performance Report will be produced in early 2015. This document will extend the 2013 interim report by providing greater detail regarding the results of the operational demonstrations conducted and summarize the corresponding benefits analysis performed using the DOE SmartGrid and Energy Storage Computational Tools. The report will conclude with a summary of the build and impact metrics reported to the DOE.

A project Final Technical Report will be produced in the first half of 2015 following the conclusion of the project and will synthesize all learnings from the entirety of project. KCP&L assumes the DOE will make it available on the same website listed previously.

### SmartGrid Demonstration Project High Level Status

The demonstration project has completed all but its final phases:

Decommissioning and Final Reporting. The final operational test was performed in November 2014. Components that will not continue are being decommissioned. Components that will continue are being moved into the appropriate production environment. Analysis for the remaining Technology Performance Reports is being performed for report issuance.

### Present Technology Roadmap Influence

Although the SmartGrid Demonstration project is not fully complete, learning has been applied to KCP&L/GMO's technology road map and business case development for several projects. KCP&L/GMO is already in process of implementing the following components in broader deployments:

- Advanced Metering Infrastructure (AMI)
- Meter Data Management (MDM)
- Outage Management System (OMS) upgrade
- Distribution SCADA "lite" integration of Sensus DA communications into the OMS Upgrade
- Enterprise Service Bus (ESB) architecture (Oracle Service Bus)
- Fault Location advanced distribution automation application as part of the OMS upgrade (a DMS-type of advanced application)
- Electric Vehicle (EV) Charging Infrastructure
- Two-way communicating programmable thermostats
- Implemented a technical Project Management Organization (PMO) to manage technology projects and coordinate integration and interoperability

AMI and EV Charging are the only items in the above list where KCP&L/GMO is using the same vendor solutions as used in the demonstration, but implementation and operational lessons still apply in all cases.

### **SECTION 5: UTILITY AFFILIATION**

(5) The electric utility shall identify and describe any affiliate or other relationship with transmission planning, designing, engineering, building, and/or construction management companies that impact or may be impacted by the electric utility. Any description and documentation requirements in sections (1) through (4) also apply to any affiliate transmission planning, designing, engineering, building, and/or construction management company or other transmission planning, designing, engineering, building, and/or construction management company currently participating in transmission works or transmission projects for and/or with the electric utility.

On April 4, 2012 Great Plains Energy ("GXP"), the holding company for both KCP&L and GMO, and American Electric Power ("AEP") announced the formation of a company to build and invest in transmission infrastructure. The new company, Transource EnergySM LLC ("Transource"), will pursue competitive transmission projects in the SPP region, the MISO and PJM regions, and potentially other regions in the future. GXP owns 13.5 percent of Transource through its newly-formed subsidiary, GPE Transmission Holding Company, LLC ("GPETHCO"). AEP owns the other 86.5 percent of Transource through its subsidiary, AEP Transmission Holding Company, LLC ("AEPTHC").

At this point, it is GXP's intent to pursue, develop, construct, and own through GPETHCO's interest in Transource – rather than through KCP&L and/or GMO – any future regional and inter-regional transmission projects subject to regional cost allocation. While it is premature to determine the specific impact on the regionally allocated costs resulting from constructing projects within Transource, it is anticipated that the partnership between GXP and AEP will provide for a financially-strong, cost-competitive, and technically-proficient transmission development entity. The scale, execution experience, and engineering expertise that Transource expects to be able to bring to the projects should provide

benefits to customers through lower construction costs, better access to capital, and operational efficiencies.					

### **SECTION 6: FUTURE TRANSMISSION PROJECTS**

(6) The electric utility shall identify and describe any transmission projects under consideration by an RTO for the electric utility's service territory.

The SPP regional transmission planning process will begin another ITP10 planning cycle in 2015, to be completed in 2017, and an ITPNT to be completed in 2016, thus there are no transmission projects under consideration at this time.
