1 Canada. In the last 20 years, I have conducted numerous national seminars on "Utility
2 Finance," "Utility Cost of Capital," "Alternative Regulatory Frameworks," and on
3 "Utility Capital Allocation," which I developed on behalf of The Management Exchange
4 Inc. in conjunction with Public Utilities Reports, Inc.

5 I have authored or co-authored several books, monographs, and articles in
6 academic scientific journals on the subject of finance. They have appeared in a variety of
7 journals, including The Journal of Finance, The Journal of Business Administration,
8 International Management Review, and Public Utilities Fortnightly. I wrote a widely
9 used treatise on regulatory finance, Utilities' Cost of Capital, Public Utilities Reports,
10 Inc., Arlington, Va. 1984. My more recent book, Regulatory Finance, is a voluminous
11 treatise on the application of finance to regulated utilities and was released by the same
12 publisher in late 1994. Missouri Public Service Commission Staff referenced this text as
13 a source for their cost of capital analysis and Staff witness Mr. Ronald Bible in his
14 November 12, 2001 deposition acknowledged it as a reliable authority.¹ I have engaged
15 in extensive consulting activities on behalf of numerous corporations, legal firms, and
16 regulatory bodies in matters of financial management and corporate litigation. Schedule
17 1 describes my professional credentials in more detail. An **Executive Summary** of my
18 testimony is included in Appendix A.

19 **Q. Have you testified on cost of capital before?**

20 **A.** Yes, I have been a cost of capital witness before more than 40 regulatory
21 bodies in North America, including the Federal Energy Regulatory Commission, and the
22 Federal Communications Commission. I have also testified before the following state

¹ MOPSC response to interrogatories 82-83 and Bible November Deposition, p. 23:16 to 24:6.

1 and provincial commissions:

Alabama	Indiana	New Brunswick	Pennsylvania
Alaska	Iowa	New Jersey	Quebec

2

3 The details of my participation in regulatory proceedings are provided in

4 Schedule I.

5 **Q. What is the purpose of this rebuttal testimony?**

6 A. I have been asked to critique Mr. Bible's cost of capital testimony from a
7 methodological perspective. Specifically, though Mr. Bible uses the names of well-
8 known methodologies in describing how he estimates a future rate of return on equity
9 ("ROE") for AmerenUE, he in fact applies these methodologies in ways that are so
10 unique, and ultimately so unreliable, that they cannot be said to be generally accepted,
11 and are far removed from the methodologies for estimating ROE that are reasonably
12 relied upon, by experts in the field. Moreover, Mr. Bible's version of these
13 methodologies has not been tested or subjected to peer review to determine their potential
14 rate of error or overall ability to provide this Commission with reliable information by
15 which to adjudicate the Staff's rate complaint. Indeed, a most striking feature of
16 Mr. Bible's unique treatment of the data to produce his estimate is that it is, as he freely
17 admits, simply of function of his own "judgment," which he apparently feels free to

1 change at any time, and does not originate from industry knowledge or any generally
2 accepted approach by experts in the field.

3 **Q. Please summarize Mr. Bible's rate of return recommendation.**

4 A. Mr. Bible recommends a return on equity ("ROE") for AmerenUE in the
5 range of 8.91% to 9.91% with a midpoint of 9.41%. In determining AmerenUE's cost of
6 common equity capital, Mr. Bible applies the constant growth discounted cash flow
7 ("DCF") method to Ameren Corporation. As separate "checks" on the results of his DCF
8 analysis applied only to this one-company sample, he applies the same DCF analysis,
9 separately, to a set of three electric utilities, and also performs Risk Premium and capital
10 asset pricing model ("CAPM") analyses. In spite of the fact that the results of his various
11 checks are significantly higher than the midpoint of his recommended range, he rejects
12 the results of these various checks because they do not amount to "double" the results of
13 his DCF calculation for Ameren. Thus, by applying a far-fetched homemade standard
14 that has no basis in statistical, economic, or financial theory, Mr. Bible has made his
15 recommendation hinge solely on the DCF method applied only to AmerenUE's parent
16 company.

17 **Q. Do you have any general comments on Mr. Bible's testimony?**

18 A. Yes. Before I engage in specific criticisms of Mr. Bible's testimony, my
19 initial reaction was that his recommended ROE of 9.41% was so radical and far-fetched
20 that it constituted a typographical error. Further reading, however, confirmed that 9.41%
21 was indeed his recommended return. My next reaction was that Mr. Bible's
22 implementation of the DCF analysis on which his recommendation rests must be

1 seriously flawed, and I proceeded to investigate the specific details of Mr. Bible's
2 methodologies.

3 My general reaction to his testimony--even ignoring his treatment of the
4 data in his calculations that only serves to produce lower numbers--is that it is extremely
5 narrow in scope. Mr. Bible has reduced and trivialized the process of determining cost of
6 capital to a simple mechanical application of the DCF formula to a one-company sample.
7 His recommendation rests entirely on the DCF methodology applied to a single
8 observation, namely, Ameren Corporation data. He ignores the results from his
9 comparable group of electric utilities and the results from other methodologies.
10 Mr. Bible has not only put all his eggs in the DCF basket, he has fashioned a totally
11 idiosyncratic DCF basket. This stands in sharp contrast with the practices of investment
12 analysts, corporate analysts, and other finance experts and professionals who generally
13 advocate the use of groups of comparable companies and several methods.

14 Also, I find that Mr. Bible's recommended 9.41% cost of equity for
15 AmerenUE lies completely outside the zone of reasonableness and well outside the zone
16 of currently authorized rates of return for electric utilities in the United States, and, as
17 such, is difficult to take seriously.² Mr. Bible's draconian cost of equity recommendation
18 of only 9.41%, if ever adopted, would result in the lowest rate of return award for an
19 electric utility in the country, and by a wide margin. I hesitate to think of its adverse
20 consequences on investors and ratepayers.

21 Finally, I find that Mr. Bible's testimony contains serious methodological

² As Schedule 17 to Ms. McShane's testimony shows, during AmerenUE's test year and update period, other States have allowed returns on equity ranging from a low of 10.50% to a high of 12.90%, for an average of 11.27%.

1 flaws, along with several inconsistencies from prior testimonies and from an earlier
2 version of the same testimony for AmerenUE.

3 **Q. What are the basic conclusions of your rebuttal to Mr. Bible's cost of**
4 **equity testimony?**

5 A. Mr. Bible's testimony is highly irregular and flawed, and grossly
6 understates AmerenUE's cost of equity. A proper application of cost of capital
7 methodologies would provide far more reasonable results. Mr. Bible's overall testimony
8 and recommendations are well outside the mainstream of both financial theory and
9 practice. As such, Mr. Bible's opinion as to an ROE for AmerenUE is so fundamentally
10 unsupported, and as a result unreliable, as to offer this Commission mere speculation,
11 guess, and conclusions founded simply on his own belief. In short, Mr. Bible's testimony
12 cannot be credited with providing the Commission with any expert analysis that can give
13 it insight in responsibly addressing the important issues in this case.

14 **Q. Please summarize your specific criticisms of Mr. Bible's testimony.**

15 A. I have several specific criticisms:

16 1. **Allowed returns far out of the mainstream.** Mr. Bible's
17 recommended range is well out of line with rate of return awards in the industry, and lies
18 completely outside the zone of currently allowed rates of return for utilities in the United
19 States.

20 2. **An unprecedented "double" standard to "check" the DCF**
21 **estimate.** Mr. Bible believes that results from his Risk Premium and CAPM analyses
22 suggest a problem with his DCF calculation only if the results of those analyses are "two
23 times" his DCF result. This standard -- that is his alone and has no source other than his

1 “judgment” – is so unreasonably broad as to make his Risk Premium and CAPM analyses
2 wholly meaningless as checks on this DCF work, a consequence he freely admits.
3 Moreover, this standard – essentially a range of $\pm 9.41\%$ around his DCF-based
4 recommendation -- is utterly arbitrary, as can be seen by comparing it to the range he
5 claims, also without justification, is appropriate for AmerenUE’s cost of capital, which is
6 $\pm 0.5\%$ around his midpoint.

7 **3. Inappropriate reliance on a single method.** As Mr. Bible
8 admits, his “double” standard reduces the other methods he purportedly uses to “check”
9 his DCF result to irrelevance. In truth then, Mr. Bible exclusively relies on the DCF
10 method, an approach wholly at odds with recognized standards for cost of capital
11 analysis.

12 **4. Unreliable sample size.** Mr. Bible's one-company DCF
13 calculation that underlies his ROE recommendation produces highly unreliable results. A
14 DCF estimate based on only one observation is statistically invalid, violates the Central
15 Limit Theorem, and violates the fundamental precepts of rate of return regulation
16 embodied in the *Bluefield* and *Hope* landmark cases. Similarly, Mr. Bible's sample of
17 only three comparable electric utilities to check his DCF estimate is statistically invalid,
18 and, at bottom, produces highly unreliable results.

19 **5. Overemphasis on historical growth rates.** Mr. Bible relies
20 inappropriately on electric utility historical growth data in his DCF analysis despite sea
21 changes occurring in the industry that make the past a very uncertain basis by which to
22 estimate future rates of return. Moreover, the historical growth rates that Mr. Bible uses
23 in his DCF analysis are redundant since historical growth patterns are already reflected in

1 analysts' growth forecasts, which he also uses. Compounding this fundamental flaw,
2 Mr. Bible relies on historical data to do his calculations notwithstanding the fact that
3 Ameren and two of the three comparable companies he selected have experienced recent
4 mergers. As a result, data drawn from before these mergers is not comparable to data
5 from after them, as the sources of this data expressly warn. Also, the stock price
6 Mr. Bible uses in his DCF analysis is predicated on analysts' growth forecasts and not on
7 historical growth rates.

8 In addition, Mr. Bible employs historical and projected dividend growth
9 in his DCF analysis even though, as he should know, electric utilities are reducing
10 dividend payouts. Because electric utilities are expected to lower their dividend payout
11 ratio over the next several years in response to the gradual penetration of competition in
12 the revenue stream and to the rising risk due to regulatory restructuring, dividend growth
13 numbers embody a downward prejudice, and can no longer accurately convey useful
14 information about the future economic activity of a utility. As a result, the use of historic
15 or projected dividend growth (rather than earnings growth) is inappropriate in using the
16 DCF model today, for they can only serve to artificially depress the results of the
17 resulting estimate. Earnings growth projections are far more relevant.

18 **6. Downward-biased CAPM beta estimate.** Mr. Bible's beta
19 estimate is downward-biased because current changes in the risk fundamentals of the
20 electric utility industry due to the introduction of competition, deregulation, and
21 restructuring are not fully reflected in the historical betas on which he relies.

22 **7. Erroneously calculated CAPM market risk premium.**

23 Mr. Bible's estimate of the market risk premium erroneously relies in part on geometric

1 averages of historical market returns rather than on the correct arithmetic average.
2 Similarly, Mr. Bible incorrectly relies on total returns instead of income returns on long-
3 term government bonds to estimate the market risk premium.

4 **ALLOWED RETURNS**

5 **Q. Is Mr. Bible's rate of return recommendation compatible with**
6 **currently allowed returns in the electric utility industry?**

7 A. No, it is not. Allowed returns, while certainly not a precise indication of a
8 particular company's cost of equity capital, are nevertheless important determinants of
9 investor growth perceptions and the approximate range of reasonable returns. They also
10 serve to provide some perspective on the validity and reasonableness of Mr. Bible's
11 recommendation.

12 The allowed return in the electric utility industry outside of Missouri
13 during AmerenUE's test year and update period ranged from 10.50% to 12.90%. (See
14 McShane Schedule 17.) This exceeds by a substantial margin Mr. Bible's anemic
15 recommended ROE of 9.41% for AmerenUE. I also have examined the returns currently
16 allowed on common equity for the three electric utilities in Mr. Bible's very small sample
17 group as reported in C.A. Turner Utility Reports survey for April 2002. The currently
18 authorized ROE for Mr. Bible's three-company sample is 11.1%, 11.7%, and 11.0%, for
19 Allegheny Energy, Alliant Energy, and Cinergy, respectively. In short, Mr. Bible's
20 recommendation is so far outside the zone of the currently allowed rates of return for his
21 comparable companies, and so far outside the mainstream of authorized returns for
22 electric utilities, that it is difficult to take seriously.

THE "DOUBLE" STANDARD

1
2 **Q. Does Mr. Bible rely on a reasonable standard in judging his cost of**
3 **equity estimates?**

4 A. Absolutely not. Mr. Bible chose to rely on an arbitrary standard that is
5 purely his, so that there is no way in which results other than the DCF applied to a single
6 company can be taken into account. According to Mr. Bible, he would only question his
7 recommendation if his results from other methods or results from comparable companies
8 were "twice as much,"³ as his solitary DCF calculation for Ameren alone. Indeed,
9 Mr. Bible has been quite emphatic about rigidly applying this standard, as is illustrated by
10 this exchange in one of his depositions:

11 Q. In your deposition testimony last time around I believe you
12 said that those crosschecks would not cause you to change
13 or reconsider your DCF estimate unless they were double
14 your DCF estimate.

15
16 Is that pretty much how, then, interest rates might affect
17 your DCF estimate?

18
19 A. No. I said that – what I actually said in the previous
20 deposition was, unless they doubled, it wouldn't cause me
21 to go back and rethink or even look at the DCF. I mean,
22 even if interest rates doubled, I'm not going to go back and
23 change my DCF model just because of that.⁴

24
25 This standard is purely Mr. Bible's opinion and is not used by any
26 reputable financial analysts. Mr. Bible's "double" standard also is not used by other
27 Missouri Public Utility Service Commission Staff as evidenced by the following
28 exchange that took place during Mr. Bible's deposition:

29 Q. In that judgment that we're talking about in terms of when you
30 believe that the comparable calculations are too far removed,

³ See Bible November Deposition, p. 131:22 to 132:1.

⁴ Bible April Deposition, p. 10:4 to 15.

1 your judgment of twice the DCF results, is that your perspective
2 or is that a practice that is followed by other members of the
3 Staff?

4
5 A. That's my perspective.

6
7 Q. Do you know how other Staff members approach that same
8 question?

9
10 A. Not offhand I don't, no.

11
12 Q. Have you ever talked to them about it?

13
14 A. Yes.

15
16 Q. And do you have any kind of recollection of how other Staff
17 members approach that?

18
19 A. As far as a specific number? No.⁵
20

21 **Q. What are the consequences of Mr. Bible's "double" standard?**

22 A. This "double" standard renders any test of Mr. Bible's recommendation
23 irrelevant as any other test results could only question the validity of the 9.41 % return on
24 equity if these other calculations came up with a cost of equity above 18.8 %. According
25 to Mr. Bible, then, a Risk Premium or CAPM result of, say, 18%, would not suggest his
26 9.41% DCF result was inaccurate or even unreasonable. He would not even "look" at his
27 DCF calculation to try to understand such a wide disparity in these results.

28 Logically, this must also mean that any rate of return results less than
29 18.8% are as reasonable as Mr. Bible's midpoint recommendation. That, of course,
30 would also mean that AmerenUE's current return and rates are reasonable as well. If
31 Mr. Bible's "double" standard is right, then, his DCF estimate for ROE cannot support
32 the Staff's rate proposal. If it is wrong, Mr. Bible's own Risk Premium and CAPM

⁵ Bible November Deposition, p. 136:14 to 137:2.

1 "checks" show his DCF result to be fundamentally flawed, and his DCF estimate even
2 more obviously fails to support that rate proposal. Either way, the Staff has, with their
3 rate of return testimony, fallen far short of meeting their burden under their complaint to
4 prove that the massive rate reduction they seek is warranted or lawful.

5 Furthermore, under this standard, under which the results of other
6 methodologies are rejected unless they are double the DCF result, calculations
7 purportedly undertaken as a "cross check" will almost never have any impact on an ROE
8 estimate, or serve to support the accuracy of the DCF estimate in any way. This certainly
9 was the case here, as Mr. Bible repeatedly emphasized under questioning in his
10 deposition. For example, when Mr. Bible was forced to admit that he has no real
11 knowledge of the comparable companies he used in his calculations, he pointed out:

12 And, again, your line of questioning is insignificant because I
13 don't use this to determine directly the return on equity and rate
14 of return for the Company.⁶
15

16 Mr. Bible could not have been more candid in underscoring that his
17 "double" standard ultimately meant his "checks" had no impact on his rate of return
18 recommendation:

19 Q. So the results from any of your other – as you've made very
20 clear, the results from your other methods didn't inform that
21 the historical growth rates or the projected growth rates,
22 those ranges didn't shape your judgment at all about this?
23

24 A. No. Like I said, the CAPM, the risk premium, the
25 comparable company analysis, those don't factor directly
26 into the calculations that I do for return on equity and rate
27 of return for AmerenUE.⁷
28

⁶ Bible April Deposition, p. 28:25 to 29:3.

⁷ Bible April Deposition, p. 53:10 to 18.

1 Given Mr. Bible's unique and arbitrary standard, he is surely correct that
2 there is no way in which his estimate of the cost of equity can be influenced by methods
3 other than his DCF calculation applied solely to Ameren itself. This approach clearly is
4 outside the accepted standards in financial economics and makes Mr. Bible's
5 recommendation highly unreliable.

6 **Q. Does the arbitrariness of Mr. Bible's "double" standard have broader**
7 **implications for the reasonableness of his recommended range for return on equity?**

8 A. Yes. Mr. Bible recommends that a reasonable range for AmerenUE's
9 return on equity is his midpoint of 9.41% \pm 50 basis points (or 0.5%). It is standard
10 practice for the width of an analyst's recommended range to be based on, or informed by,
11 the range of results from different methodologies, the application of various
12 methodologies to comparable companies, or the variation in projected growth rates used
13 in the DCF calculation. Of course here, Mr. Bible has already adopted his "double"
14 standard for evaluating the results of other "cross check" methodologies. If this "double"
15 standard were used to create his ROE range, Mr. Bible would be proposing a range for
16 AmerenUE's ROE around his midpoint of \pm 9.41%, which, instead of a range of 50 basis
17 points (0.5%), represents a swing of 9.41 basis points (9.41%), within which
18 AmerenUE's current rates more than comfortably fit. Why one range should be so tight,
19 while the other is so broad, Mr. Bible does not even attempt to explain. His only
20 justification for his choice of the 50 basis point range for his ROE recommendation is
21 that he has chosen it, as he made clear in the following exchange in his deposition:

22 Q. Well, is there anything other than your own thinking that
23 you refer to, whether it's a treatise or any other scholar or a
24 policy of the staff to determine that plus or minus .5
25 percent is a reasonable range?

1
2 A. No, there is no specific reference. From my experience
3 and my judgment, that's an adequate number to use around
4 a midpoint to develop a range.⁸
5

6 Such bald, unsupported claims simply cannot pass muster as professional,
7 competent analysis in the eyes of mainstream investment analysts, corporate analysts, and
8 other finance professionals, and should not be treated as such by this Commission.
9 Indeed, such subjective, personal opinion testimony as to a proper ROE for AmerenUE
10 can only lead the Commission into the most arbitrary and capricious rate-setting.

11 **INAPPROPRIATE RELIANCE ON A SINGLE METHOD**

12 **Q. Mr. Bible has limited the cost of equity estimation process to one**
13 **methodology, namely, DCF. Does his failure to consider the results of other**
14 **methods in his final recommendation make his results unreliable, if not highly**
15 **biased?**

16 A. Yes, it does. A fundamental problem in his testimony is the lack of
17 corroborating evidence. There is simply no objective cross check on his one DCF result,
18 given the arbitrary and meaningless standard he has set to assess the reasonableness of
19 such checks. The 9.41% cost of equity recommended by Mr. Bible is unreasonably low,
20 and is not a reliable estimate of AmerenUE's cost of equity capital. Had Mr. Bible
21 correctly used all the market data and financial models available to him, his estimate
22 would be significantly higher.

23 There are at least four broad generic methodologies available to measure
24 the cost of equity: DCF, Risk Premium, and CAPM, which are market-oriented; and
25 Comparable Earnings, which is accounting-oriented. Each generic market-based

⁸ Bible April Deposition, p. 52:5-12.

1 methodology in turn contains several variants. Mr. Bible has chosen to rely on his own,
2 idiosyncratic and erroneous application of one method, namely the constant growth (or
3 standard) DCF method applied to one company.

4 However, when estimating equity costs, which essentially deals with the
5 estimation of something that cannot be objectively and certainly known, that is, investor
6 expectations, no single methodology provides foolproof results. Each methodology
7 requires the exercise of considerable judgment on the reasonableness of the assumptions
8 underlying the methodology and on the reasonableness of the proxies used to validate the
9 theory. The well-recognized failure of the traditional DCF model to account for changes
10 in relative market valuation is a vivid example of the potential shortcomings of the DCF
11 model when applied to a given company, as I show below. It follows that more than one
12 methodology should be employed in arriving at a reliable judgment on the cost of equity
13 and that these methodologies should be applied across a spectrum of comparable-risk
14 companies.

15 As I discuss extensively in Chapter 9 of my book, Regulatory Finance,
16 there is no single model that conclusively determines or estimates the expected return for
17 an individual company. Each model possesses its own way of examining investor
18 behavior, its own premises, and its own set of simplifications of reality. Each model
19 proceeds from different fundamental premises which cannot be validated empirically.
20 Investors do not subscribe to any one method, nor does the stock price reflect the
21 application of any one single method by the price-setting investor.

22 Absent any hard evidence as to which method outdoes the other, all
23 relevant evidence should be used and weighted equally in order to minimize judgmental

1 error, measurement error, and conceptual infirmities. I submit that the Commission
2 should rely on the results of a variety of methods applied to a variety of comparable
3 groups, and not, as Mr. Bible has done, on one particular method applied to one
4 company. A single DCF result is not a reliable predictor of the stock price and of the cost
5 of equity reflected in that price, just as there is no guarantee that a single CAPM or Risk
6 Premium result could not constitute a reliable explanation of that stock price or the cost
7 of equity.

8 **Q. Does the financial literature support the use of more than a single**
9 **method?**

10 **A.** Yes. Authoritative financial literature strongly supports the use of
11 multiple methods. For example, Professor Brigham, a widely respected scholar and
12 finance academician, asserts:

13 In practical work, it is often best to use all three methods -
14 CAPM, bond yield plus risk premium, and DCF - and then
15 apply judgement when the methods produce different results.
16 People experienced in estimating capital costs recognize that
17 both careful analysis and some very fine judgements are
18 required. It would be nice to pretend that these judgements are
19 unnecessary and to specify an easy, precise way of determining
20 the exact cost of equity capital. Unfortunately, this is not
21 possible.⁹

22
23 In a subsequent edition of his best-selling corporate finance textbook,
24 Dr. Brigham discusses the various methods used in estimating the cost of common equity
25 capital, and states:

26 However, three methods can be used: (1) the Capital Asset
27 Pricing Model (CAPM), (2) the discounted cash flow (DCF)
28 model, and (3) the bond-yield-plus-risk-premium approach.
29 These methods should not be regarded as mutually exclusive -

⁹ Eugene F. Brigham and Louis C. Gapenski, Financial Management Theory and Practice, p. 256 (4th ed., Dryden Press, Chicago, 1985)

1 no one dominates the others, and all are subject to error when
2 used in practice. Therefore, when faced with the task of
3 estimating a company' cost of equity, we generally use all three
4 methods.....¹⁰

5
6 Mr. Bible should have heeded to Professor Brigham's admonitions in this
7 regard as well.

8 Another prominent finance scholar, Professor Stewart Myers, in his best
9 selling corporate finance textbook, points out:

10 The constant growth formula and the capital asset pricing model
11 are two different ways of getting a handle on the same
12 problem.¹¹

13
14 In an earlier article, Professor Myers explains:

15 Use more than one model when you can. Because estimating
16 the opportunity cost of capital is difficult, only a fool throws
17 away useful information. That means you should not use any
18 one model or measure mechanically and exclusively. Beta is
19 helpful as one tool in a kit, to be used in parallel with DCF
20 models or other techniques for interpreting capital market
21 data.¹²

22
23 **Q. Doesn't the broad usage of the DCF methodology in past regulatory**
24 **proceedings make it superior to other methods?**

25 A. No, it does not. While the DCF model has been well entrenched in
26 financial theory in the past, uncritical acceptance of the standard DCF equation vests the
27 model with a degree of infallibility that simply is not there.

¹⁰ Id. at p. 348.

¹¹ R. A. Brealey and S. C. Myers, Principles of Corporate Finance, p. 182 (3rd ed., McGraw Hill, New York, 1988)

¹² S. C. Myers, "On the Use of Modern Portfolio Theory in Public Utility Rate Cases: Comment," Financial Management, p. 67 (Autumn 1978).

1 One of the leading experts on regulation, Dr. C. Phillips discusses the
2 dangers of relying solely on the DCF model:

3 [U]se of the DCF model for regulatory purposes involves both
4 theoretical and practical difficulties. The theoretical issues
5 include the assumption of a constant retention ratio (i.e. a fixed
6 payout ratio) and the assumption that dividends will continue to
7 grow at a rate 'g' in perpetuity. Neither of these assumptions
8 has any validity, particularly in recent years. Further, the
9 investors' capitalization rate and the cost of equity capital to a
10 utility for application to book value (i.e. an original cost rate
11 base) are identical only when market price is equal to book
12 value. Indeed, DCF advocates assume that if the market price
13 of a utility's common stock exceeds its book value, the
14 allowable rate of return on common equity is too high and
15 should be lowered; and vice versa. Many question the
16 assumption that market price should equal book value, believing
17 that "the earnings of utilities should be sufficiently high to
18 achieve market-to-book ratios which are consistent with those
19 prevailing for stocks of unregulated companies.

20
21 ...[T]here remains the circularity problem: Since regulation
22 establishes a level of authorized earnings which, in turn,
23 implicitly influences dividends per share, estimation of the
24 growth rate from such data is an inherently circular process.
25 For all of these reasons, the DCF model 'suggests a degree of
26 precision which is in fact not present' and leaves 'wide room for
27 controversy about the level of k [cost of equity]'.¹³
28

29 Sole reliance on the DCF model simply ignores the capital market
30 evidence and investors' use of other theoretical frameworks such as the CAPM. The
31 DCF model is only one of many tools to be employed in conjunction with other methods
32 to estimate the cost of equity. It is not a superior methodology which supplants other
33 financial theory and market evidence.

34 **Q. Should the underlying assumptions of the DCF model be treated with**
35 **caution?**

¹³ C. F. Phillips, The Regulation of Public Utilities Theory and Practice, pp. 376-77. (Public Utilities Reports, Inc., 1988) pp. 376-77. [Footnotes omitted]

1 A. Yes, they should, particularly in today's rapidly changing utility industry.
2 Notwithstanding the fundamental thesis that several methods and/or variants of such
3 methods should be used in measuring equity costs, Mr. Bible has exclusively relied on a
4 methodology that, to those familiar with the industry and the accepted norms for
5 estimating the cost of equity, is dangerously fragile at this time.

6 Several fundamental and structural changes have transformed the energy
7 utility industry from the times when the standard DCF model and its assumptions were
8 developed. Deregulation, increased competition triggered by national policy, accounting
9 rule changes, changes in customer attitudes regarding utility services, the evolution of
10 alternative energy sources, and mergers-acquisitions have all influenced stock prices in
11 ways vastly different from the early assumptions of the DCF model. These changes
12 suggest that some of the raw assumptions underlying the standard DCF model,
13 particularly that of constant growth and constant relative market valuation, are of
14 questionable pertinence at this point in time for utility stocks, and that the DCF model
15 should be complemented, at a minimum, by alternate methodologies to estimate the cost
16 of common equity.

17 Similarly, the historical growth rates that are employed by Mr. Bible in
18 implementing the growth component of the DCF model are downward-biased by the
19 impact of increased competition on eroding margins, diversification and restructuring
20 activities in recent years. This is addressed at length in my discussion of Mr. Bible's use
21 of historical growth rates in Section 5 below.

22 **Q. Is the constant relative market valuation assumption inherent in the**
23 **DCF model always reasonable?**

1 A. No. Caution must also be exercised when implementing the standard DCF
2 model in a mechanistic fashion, for it may fail to recognize changes in relative market
3 valuations. The traditional DCF model is not equipped to deal with surges in market-to-
4 book (M/B) and price-earnings (P/E) ratios.

5 The standard DCF model assumes a constant market valuation multiple,
6 that is, a constant P/E ratio and a constant M/B ratio. That is, the model assumes that
7 investors expect the ratio of market price to dividends (or earnings) in any given year to
8 be the same as the current ratio of market price to dividend (or earnings) ratio, and that
9 the stock price will grow at the same rate as the book value. This must be true if the
10 infinite growth assumption is made.

11 This assumption is somewhat unrealistic under current conditions. The
12 DCF model is not equipped to deal with sudden surges in M/B and P/E ratios, as was
13 experienced by several utility stocks, in recent years. The ratios are anything but
14 constant, thus violating one of the crucial assumptions of the DCF model.

15 **Q. Can you illustrate the impact of volatile market-to-book ratios on the**
16 **DCF market return by means of a simple example?**

17 A. Application of the DCF model produces estimates of common equity cost
18 that are consistent with investors' expected return only when stock price and book value
19 are reasonably similar, that is, when the M/B is close to unity. As shown below,
20 application of the standard DCF model to utility stocks understates the investor's
21 expected return when the M/B ratio of a given stock exceeds unity. This is particularly
22 relevant in the current capital market environment where utility stocks are trading at
23 M/B ratios well above unity. The converse is also true; that is, the DCF model overstates

1 the investor's return when the stock's M/B ratio is less than unity. The reason for the
2 distortion is that the DCF market return is applied to a book value rate base by the
3 regulator, that is, a utility's earnings are limited to earnings on a book value rate base.

4 The simple numerical illustration shown in the table below demonstrates
5 the result of applying a market value cost rate to book value rate base under three
6 different M/B scenarios. The three columns correspond to three M/B situations: the stock
7 trades below, equal to, and above book value, respectively. The last situation is
8 noteworthy and representative of the current capital market environment. The DCF cost
9 rate of 10%, made up of a 5% dividend yield and a 5% growth rate, is applied to the book
10 value rate base of \$50 to produce \$5.00 of earnings. Of the \$5.00 of earnings, the full
11 \$5.00 are required for dividends to produce a dividend yield of 5% on a stock price of
12 \$100.00, and no dollars are available for growth. The investor's return is therefore only
13 5% versus his required return of 10%. A DCF cost rate of 10%, which implies \$10.00 of
14 earnings, translates to only \$5.00 of earnings on book value, a 5% return. The situation is
15 reversed in the first column when the stock trades below book value. The \$5.00 of
16 earnings is more than enough to satisfy the investor's dividend requirements of \$1.25,
17 leaving \$3.75 for growth, for a total return of 20%. This is because the DCF cost rate is
18 applied to a book value rate base well above the market price. Therefore, the DCF cost
19 rate produces less than the investor's required return when stock prices are well above
20 book, as is the case presently.

21 ***EFFECT OF MARKET-TO-BOOK RATIO ON MARKET RETURN***
22
23

	<i>Situation 1</i>	<i>Situation 2</i>	<i>Situation 3</i>
1 Initial purchase price	\$25.00	\$50.00	\$100.00
2 Initial book value	\$50.00	\$50.00	\$50.00
3 Initial M/B	0.50	1.00	2.00

4	DCF Return	10% = 5% + 5%	10.00%	10.00%	10.00%
5	Dollar Return		\$5.00	\$5.00	\$5.00
6	Dollar Dividends	5% Yield	\$1.25	\$2.50	\$5.00
7	Dollar Growth	5% Growth	\$3.75	\$2.50	\$0.00
8	Market Return		20.00%	10.00%	5.00%

1

2 In summary, caution and judgment are required in interpreting the results
3 of the DCF model because of (1) the effect of changes in risk and growth on electric
4 utilities, (2) the fragile applicability of the DCF model to utility stocks in the current
5 capital market environment, and (3) the practical difficulties associated with the growth
6 component of the DCF model. Hence, there is a clear need to go beyond the DCF results
7 and take into account the results produced by alternate methodologies in arriving at a
8 ROE recommendation, as Mr. Bible should have done.

9

UNRELIABLE SAMPLE SIZE

10 **Q. Please explain why Mr. Bible's sample size leads to unreliable**
11 **recommendations.**

12 A. Mr. Bible's ROE recommendation hinges solely on the results of a DCF
13 analysis performed on only one company, namely, AmerenUE's parent company,
14 Ameren. Results from comparable companies are not given any weight in forming his
15 recommendation, given the impossible standard he has set for assessing the
16 reasonableness of his recommendation.

17 **Q. Does this approach for estimating the rate of return based on the**
18 **results for one company square with the fundamental precepts of regulation?**

19 A. No, it does not. The heart of utility regulation is the setting of just and
20 reasonable rates by way of a fair and reasonable return. The landmark U. S. Supreme
21 Court *Bluefield* and *Hope* cases set the foundations for the notion of a fair return and the

1 standard against which just reasonable rates are measured. As the Court explained in

2 *Bluefield*:

3 A public utility is entitled to such rates as will permit it to earn
4 a return on the value of the property which it employs for the
5 convenience of the public equal to that generally being made at
6 the same time and in the same general part of the country on
7 investments in other business undertakings which are attended by
8 corresponding risks and uncertainties ...¹⁴
9

10 In the *Hope* case, the Supreme Court likewise stated:

11 From the investor or company point of view it is important
12 that there be enough revenue not only for operating expenses
13 but also for the capital costs of the business. These include
14 service on the debt and dividends on the stock ... By that
15 standard the return to the equity owner should be commensurate
16 with returns on investments in other enterprises having
17 corresponding risks.¹⁵
18

19 Mr. Bible appears to rely on these decisions as he quotes the same passage
20 from the *Bluefield* case on page 5 and refers to the "corresponding risk" in the Supreme
21 Court's discussion of the *Hope* case on p. 6 line 9.

22 The economic logic underlying these standards is straightforward. There
23 is an opportunity cost associated with the funds that capital suppliers provide a public
24 utility. That cost is the expected return foregone by not investing in other enterprises of
25 corresponding risks. Thus, the expected rate of return on a public utility's equity capital
26 should equal the expected rate of return on equity of other firms having comparable risks.

27 In contrast to these standards, the core of Mr. Bible's approach to setting a
28 fair and reasonable rate of return for a public utility is to rely exclusively on a DCF

¹⁴ *Bluefield Water Works & Improvement Company v. Public Service Comm.*, 262 U.S. 679 (1923) at 692-3.

¹⁵ *Federal Power Commission et al v. Hope Natural Gas Co.*, 320 U.S. 591 (1944) at 603.

1 analysis of a one-company sample. Results from comparable companies are not given
2 any weight in arriving at his final ROE recommendation. Mr. Bible's exclusive reliance
3 on Ameren as his sample does not square well with the *Hope* and *Bluefield* guidelines.
4 The rate of return standard, as expounded clearly in *Hope* and *Bluefield*, is to allow an
5 equity return commensurate with returns on investments in other enterprises having
6 corresponding risks. This fundamental paradigm clearly suggests the analysis of
7 comparable risk investments.

8 Not only is Mr. Bible's view in direct violation of the fundamental
9 precepts of the *Hope* and *Bluefield* standards of fair return, it is also in contradiction of
10 the economic concept of opportunity cost, which clearly hinges on the use of comparable
11 investment opportunities. Moreover, it is transparent that the DCF model should be
12 applied to comparable risk firms in recognition of the fact that utilizing a portfolio of
13 similar companies acts to reduce the chance of either overestimating or underestimating
14 the cost of equity. The academic and professional literature has a long and rich tradition
15 of applying cost of capital methodologies on a sample of comparable companies rather
16 than on a one-company sample. For example, as Professors Brealey and Myers
17 explained:

18 The simple constant-growth DCF formula is an extremely useful
19 rule of thumb, but no more than that. Naive trust in the formula
20 has led many financial analysts to silly conclusions. We have
21 stressed the difficulty of estimating [the cost of equity] by
22 analysis of one stock only. Try to use a large sample of
23 equivalent-risk securities. Even that may not work, but at least it
24 gives an analyst a fighting chance, because the inevitable errors
25 in estimating [the cost of equity] for a single security tend to
26 balance out across a broad sample.¹⁶
27

¹⁶ Brealey & Myers (6th ed.), supra, at 69.

1 By relying solely on a one-company estimate, the Commission would set a
2 very dangerous precedent for future ratemaking procedures. A one-company sample is
3 likely to contain a high degree of measurement error and may be distorted by short-term
4 aberrations. The Commission's hands should not be bound to one single company-
5 specific estimate of equity costs.

6 **Q. Dr. Morin, Mr. Bible did calculate DCF and CAPM results for a**
7 **group of three comparable utilities. Assuming he had given appropriate weight to**
8 **these results and assuming his results were based on appropriate calculations, is a**
9 **sample of three comparable companies sufficient to produce a reliable cost of equity**
10 **recommendation?**

11 A. No, it is not. A sample of only three comparable companies is far too
12 small, subject to measurement error, and in violation of the Central Limit Theory of
13 statistics. Moreover, the results of Mr. Bible's DCF application to his sample of three
14 utilities are clouded by recent mergers for two of his sample companies, rendering the use
15 of historical growth rates highly problematic and unreliable, if not useless.

16 **Q. Is there any evidence that Mr. Bible's results are unreliable?**

17 A. Yes, there is. To illustrate the lack of reliability of the results produced
18 from such a small sample, Mr. Bible's Schedule 20 displays his various growth rates.
19 The growth rates are scattered all over, ranging from a low of 1% to a high of 10%. The
20 huge variability in the growth results demonstrates the lack of reliability in this too-
21 limited sample.

OVEREMPHASIS ON HISTORICAL GROWTH RATES

Q. Is Mr. Bible's reliance on historical growth rates appropriate for the purpose of estimating a utility's cost of equity in today's rapidly changing industry?

A. No, absolutely not. As mentioned above, the historical growth rates that are employed by Mr. Bible in implementing the growth component of the DCF model are highly inappropriate and downward-biased due to the impact of increased competition on eroding margins, diversification, and restructuring activities in recent years.

Acquisitions, startup expenses and front-end capital investments associated with diversification, a reduction of dividend payout ratios, and restructuring efforts in the light of intensifying competition in recent years have retarded and diluted historical growth rates, and such growth is not representative of many utilities' long-term growth potential.

Given the dramatic changes in the electric utility industry's operating environment, the need to be forward-looking is apparent. In this environment, historically based measures of risk and growth are necessarily unreliable, if not useless, and are likely to be downward-biased in assessing present circumstances.

Moreover, the fundamental risks of electric utilities are changing rapidly. This structural shift in risk is not fully reflected in the historical growth rates. Hence, backward-looking growth and statistical analysis fails to fully reflect the fact that the risks of electric utilities have escalated, and will only provide limited evidence that the risk and the cost of capital have increased. Therefore, caution must be exercised when applying any of the growth estimating techniques directly to recent historical utility company data. Not surprisingly, FERC has explicitly rejected the use of historical

1 growth rates. For example, FERC in its recent Opinion 445 decided to rely on IBES
2 analysts' earnings forecast and retention ratios to estimate growth.

3 Another reason for caution is that the stock price used as input in the
4 dividend yield component may be biased by structural changes and changing investor
5 expectations in the electric utility industry. Stock prices can also be influenced by
6 mergers and acquisitions possibilities, by speculation concerning asset restructurings and
7 deregulation of certain assets, and by corporate takeover rumors.

8 **Q. Please explain why Mr. Bible's use of historical growth rates in**
9 **applying the DCF model to electric utilities is inappropriate and leads to highly**
10 **biased results.**

11 A. In arriving at his proxies for the DCF growth component, Mr. Bible
12 considers 5-year and 10-year historical growth rates in dividends, book value, and
13 earnings as reported by Value Line. I disagree with the use of electric utility historical
14 growth rates at this time.

15 In a stable industry, it may be reasonable to assume that historical growth
16 rates in dividends and earnings influence investors' assessment of the long-run growth
17 rate of future dividends and earnings. However, because of sea changes in the industry,
18 historical growth rates have little relevance as proxies for future long-term growth. They
19 are downward-biased by the sluggish earnings performance and many utilities' reduction
20 of dividend payout ratios in the last decade, due to the structural transformation of the
21 electric utility business from a regulated monopoly to a competitive environment.

22 As discussed in Chapter 5 of my book, Regulatory Finance, it is highly
23 inappropriate to rely on historical growth rates when a utility or the industry is in

1 transition. If a period is characterized by non-recurrent events, historical earnings growth
2 become unrepresentative of future growth, and analysts' growth forecasts provide a more
3 realistic and representative growth proxy for what was likely to happen in the future.¹⁷ I
4 conclude that "it is perilous to apply historical growth when a utility is in a transition
5 between growth paths."¹⁸

6 In addition, Mr. Bible's calculation of historical growth rates for
7 AmerenUE is simply meaningless and deeply flawed. Mr. Bible's source for the data he
8 uses to calculate his historical growth rates, Value Line, explicitly stresses that
9 "Premerger data are for Union Electric only and are not comparable to Ameren data."¹⁹
10 Value Line comments in the same way on Alliant Energy's data and on Cinergy.²⁰ This
11 means Mr. Bible's historical growth rates are not even based on data for the same
12 company: the data prior to 1997 is for Union Electric, while the later data is for Ameren,
13 including CIPS and unregulated subsidiaries. As Value Line warns, this data is not
14 comparable. In fact, Mr. Bible admitted in depositions that he is not familiar with the
15 most basic industry developments in recent years (such as FERC Orders 888 and 2000)
16 nor with basic facts about the comparable utilities he selected.²¹ He represents that he
17 does not need to know these facts because Value Line and other financial analysts'
18 reports on which he relies have adequately considered these facts. However, this basic
19 lack of personal knowledge also means that Mr. Bible has absolutely no basis for his
20 rejection of Value Line's and other analysts' projected growth rates or for his application

¹⁷ See also Regulatory Finance, p. 149-157.

¹⁸ Id. p. 153.

¹⁹ Value Line Investment Survey, January 4, 2002 (provided by Staff in response to JJC-16).

²⁰ Value Line Investment Survey, January 4, 2002.

²¹ See Bible November Deposition, p. 107 and April Deposition, p. 28-29.

1 of historic growth rates. As Ms. McShane shows, Mr. Bible's unsupported judgment
2 serves to understate in a very material fashion his DCF results for Ameren as well as for
3 his three comparable companies. His inappropriate reliance on historic growth rates
4 serves to understate his recommended ROE by 175 basis points. I strongly recommend
5 that the Commission reject Mr. Bible's uninformed, erroneous, and highly biased results
6 and ROE recommendation.

7 As reported on page 22 of Mr. Bible's testimony, feeble historical growth
8 rates of 1.50% are certainly not representative of Ameren's long-term earning power, and
9 produce unreasonably low DCF estimates, well outside reasonable limits of probability
10 and common sense. Moreover, historical growth rates are largely redundant because such
11 historical growth patterns are already incorporated in the analysts' growth forecasts that
12 Mr. Bible also uses.

13 I therefore recommend that the Commission reject historical growth rates
14 as proxies for expected growth in the DCF calculation at this time of profound change in
15 the industry.

16 **Q. Does Mr. Bible compute his DCF growth rate for the comparable**
17 **companies in a consistent fashion in both his July 2001 and March 2002 testimony?**

18 **A.** No, he does not. In his March 2002 testimony, he inexplicably switches
19 course dramatically in computing DCF growth rates for the three comparable companies.
20 In his July 2001 testimony Mr. Bible relies directly on Value Line's earnings per share
21 growth forecast. In his most recent testimony, however, Mr. Bible averages Value Line's
22 growth projections for dividends, book value, and earnings per share. (See his Schedule
23 20 Column 4 and the Bible April Deposition, p. 37). This opportunistic switch in

1 computing growth rates – which was entirely undocumented and only acknowledged
2 when Mr. Bible was directly questioned by counsel in his deposition -- profoundly
3 reduces Mr. Bible's results. Mr. Bible's arbitrary averaging of Value Line growth
4 forecasts reduces the true Value Line forecasted earnings growth for the comparable
5 companies by 329 basis points and the estimated DCF cost of equity for the comparable
6 companies by approximately 55 basis points.²² This kind of opportunistic switch in
7 methodology is highly unsettling, disturbing, and certainly casts a dark shadow on the
8 credibility of Mr. Bible's recommendation. Moreover, as I show below, dividend growth
9 forecasts are inappropriate proxies for the long-term growth in the DCF model at this
10 time.

11 **Q. Should Mr. Bible have considered Value Line's dividend growth**
12 **forecast in his DCF analysis?**

13 A. No, he should not. It is inappropriate to use the projected dividend growth
14 of electric utilities in this industry environment. The problem with the use of Value
15 Line's dividend growth forecasts, besides the fact that these forecasts are only one
16 individual firm's forecasts, is that they are largely dominated by the anticipated dividend
17 policy of a company over the next few years, not the true growth prospects that form the
18 basis for investors' valuation of the particular company's stock.

19 **Q. What is the impact of changing dividend policies on the reliability of**
20 **dividend growth projections?**

21 A. The reason for skepticism about dividend growth projections as an
22 indication of a company's economic future is that it is widely expected that energy
23 utilities will lower their dividend payout ratio over the next several years in response to

²² See McShane Table 6 for a calculation of the 329 bps and note that 55 bps = $(1/2) \times (1/3) \times 329$ bps.

1 the gradual penetration of competition in the revenue stream. In other words, earnings
2 and dividends are not expected to grow at the same rate in the future. According to the
3 latest edition of Value Line, the expected dividend growth for the electric utility industry
4 is far less than the expected earnings growth over the next few years.

5 Whenever the dividend payout ratio is expected to change, the
6 intermediate growth rate in dividends cannot equal the long-term growth rate, because
7 dividend and earnings growth must adjust to the changing payout ratio. The DCF
8 model's underlying assumptions of constant perpetual growth and constant payout ratio
9 are clearly not met. The implementation of the standard DCF model is of questionable
10 relevance in this circumstance.

11 Because the dividend payout ratio of utilities is expected to decline, so that
12 near-term dividend growth is not representative of long-term growth prospects, only
13 earnings growth forecasts will reasonably reflect investors' valuation of a company's
14 stock and thus represent the far better growth value for use in DCF calculations.

15 For that reason, Mr. Bible's DCF results must, again, be treated with
16 caution and accorded little, if any, weight.

17 **Q. Is the consensus earnings growth forecast of analysts an appropriate**
18 **proxy for expected growth in the DCF model?**

19 A. Yes, it is. And given Mr. Bible's admitted lack of personal knowledge of
20 the industry, he should have relied exclusively on such consensus forecasts in his DCF
21 analysis. The best proxy for the growth component of the DCF model for Ameren and
22 for Mr. Bible's sample of comparable companies is the analysts' consensus forecast of
23 earnings growth. The DCF estimates based on dividend growth and Mr. Bible's

1 erroneous historic growth calculations should be discarded for reasons cited earlier.
2 Mr. Bible should have relied only on analysts' consensus earnings growth forecasts as
3 proxies for investors' growth expectations in applying the DCF model. These forecasts
4 are made by large reputable organizations, and the data are readily available to investors
5 and are representative of the consensus view of investors.

6 **Q. What does the published academic literature say on the subject of**
7 **using analyst growth forecasts in the DCF model?**

8 A. Published studies in the academic literature demonstrate that growth
9 forecasts made by security analysts are reasonable indicators of investor expectations,
10 and that investors rely on analysts' forecasts. Cragg and Malkiel [*Expectations and the*
11 *Structure of Share Prices*", Chicago: University of Chicago Press, 1982] present detailed
12 empirical evidence that the average analysts' expectation is more similar to expectations
13 being reflected in the marketplace than are historical growth rates. Cragg and Malkiel
14 show that historical growth rates do not contain any information that is not already
15 reflected in analysts' growth forecasts. A study by Professors Vander Weide and
16 Carleton, "*Investor Growth Expectations: Analysts vs. History*," (The Journal of Portfolio
17 Management, Spring 1988), also confirms the superiority of analysts' forecasts over
18 historical growth extrapolations. Another study by Timme & Eiseman, "*On the Use of*
19 *Consensus Forecasts of Growth in the Constant Growth Model: The Case of Electric*
20 *Utilities*," (Financial Management, Winter 1989), produces similar results.

21 Several studies in the 1990s suggest that analysts either systematically
22 under-react or over-react to new information. However, these findings do not contradict

1 the earlier literature's conclusion that analysts' earnings forecasts are a better proxy for
2 investors' growth expectations than historical averages.

3 **DOWNWARD-BIASED CAPM BETA ESTIMATES**

4 **Q. Dr. Morin, do you agree with Mr. Bible's estimates of "beta" as used**
5 **in the Capital Asset Pricing Model or "CAPM"?**

6 A. No, I do not. Mr. Bible utilizes the historical beta estimates reported by
7 Value Line for Ameren and each of his three comparable companies in his electric utility
8 sample. These historical betas of electric utilities should be ignored at this time for
9 important reasons. The electric utility industry is highly unstable at this time, given the
10 significant changes in the industry. Electric utility stocks have become increasingly
11 disconnected from overall stock market movements. Electric utility stocks "have a life of
12 their own" and have been increasingly driven by industry-specific factors in recent years,
13 including corporate restructurings, mergers, asset divestitures, and regulatory change.
14 The effects of changes in the level of risk in measured betas, hence on cost of capital,
15 have been analyzed in the empirical finance literature, and this research has shown that a
16 "random shock" that changes the true beta cannot be immediately measured by a beta
17 estimated from historical data. For example, rising investor risk perceptions cause a
18 decline in stock prices, leading to a decline in utility stock returns relative to the returns
19 of the overall market, which in turn produces low historical betas even though investors
20 expected beta and the associated cost of equity has not declined.

21 The historical betas of electric utilities are downward-biased from a
22 technical perspective. Ongoing changes in risk fundamentals are not yet being fully
23 reflected in historical beta estimates. The historical betas of approximately 0.56 reported

1 by Value Line for the electric utility industry are not indicative of future trends in the
2 industry. By construction, backward-looking betas are sluggish in detecting fundamental
3 future changes in a company's risk. For example, if an electric utility suddenly
4 experiences a quantum increase in its business risk, as is the case under the stimulus of
5 ongoing restructuring and competition, one expects an increase in beta. However, if 60
6 months of return data are used to estimate beta, only one of the 60 data points reflects the
7 new information, one month after the company experiences its increase in business risk.
8 Thus, the change in risk only has a minor effect on the historical beta. Even one year
9 later, only 12 of the 60 return points reflect the event.

10 This type of bias certainly applies to electric utilities today. The
11 fundamental risks of electric utilities are changing rapidly. A beta truly reflective of
12 market conditions is likely to be higher than that implied by a simple comparison of
13 historical risk measures. Given the dramatic changes occurring in the electric utility
14 operating environment, the need to be forward-looking is apparent.

15 **ERRONEOUSLY CALCULATED CAPM MARKET RISK PREMIUM**

16 **Q. Do you agree with Mr. Bible's approach to estimating the market risk**
17 **premium?**

18 **A.** No, I do not. As shown on page 26 of his testimony, Mr. Bible determines
19 two market risk premium estimates. First, he determines a long-term market risk
20 premium over the period 1926-2000 using the difference between the arithmetic average
21 of the return on stocks and the total return on long-term Treasury bonds reported in the
22 Ibbotson Associates 2001 Valuation Yearbook. Second, he determines a market risk
23 premium over the period 1991-2000 using the difference between the geometric average

1 of the return on stocks and the total return on long-term Treasury bonds. Both the use of
2 a geometric average and the use of the total return on long-term government bonds are
3 incorrect.

4 **Q. Please explain why Mr. Bible's use of a geometric average is incorrect.**

5 A. Only the use of arithmetic means is correct for forecasting
6 purposes and for estimating the cost of capital. As demonstrated formally in
7 Chapter 11 of my book, Regulatory Finance, pp. 275-277, and in Brealey &
8 Myers best-selling corporate finance textbook, Principles of Corporate Finance,
9 (6th ed.), pp. 157-160, only arithmetic averages can be used as estimates of cost of
10 capital and market risk premium, and that the geometric mean is not an
11 appropriate measure of the market risk premium. Similarly, Ibbotson Associates,
12 Mr. Bible's own source of data, state that:

13 For use as the expected equity risk premium in either the
14 CAPM or the building block approach, the arithmetic mean
15 or the simple difference of the arithmetic means of stock
16 market returns and riskless rates is the relevant number.²³

17 Surprisingly, this error is committed by Mr. Bible in spite of the fact that
18 the widely-used Ibbotson Associates publication from which his market risk premium
19 estimate is derived contains a detailed and rigorous explanation why it is incorrect to use
20 geometric averages for the purposes estimating the cost of capital.²⁴

22 **Q. Why is the arithmetic mean the correct method for estimating the cost**
23 **of capital?**

²³ Ibbotson Associates: Stocks, Bonds, Bills, and Inflation Valuation Edition 2001 Yearbook p. 61.

²⁴ Ibbotson Associates: Stocks, Bonds, Bills, and Inflation Valuation Edition 2001 Yearbook p. 61-63.

1 A. The use of the arithmetic mean appears counter-intuitive at first glance,
2 because we commonly use the geometric mean return to measure the average annual
3 achieved return over some time period. For example, the long-term performance of a
4 portfolio is frequently assessed using the geometric mean return. The achieved or
5 retrospective return is measured by the geometric average.

6 But performance appraisal is one thing, and cost of capital estimation is
7 another matter entirely. In estimating the cost of capital, the goal is to obtain the rate of
8 return that investors expect, that is, a target rate of return. On average, investors expect
9 to achieve their target return prospectively. This target expected return is best captured
10 by the arithmetic average. In statistical parlance, the arithmetic average is the unbiased
11 measure of the expected value of repeated observations of a random variable. This is not
12 the case for the geometric mean.

13 The geometric mean answers the question of what constant return you
14 would have had to achieve in each year to have your investment growth match the return
15 achieved by the stock market. In contrast, the arithmetic mean answers the question of
16 what growth rate is the best estimate of the future amount of money that will be produced
17 by continually reinvesting in the stock market. It is the rate of return which, compounded
18 over multiple periods, gives the mean of the probability distribution of ending wealth. As
19 a consequence, only the arithmetic mean is appropriate for estimations of the cost of
20 capital. Appendix I in Chapter 11 of my book, Regulatory Finance provides a numerical
21 example to show that the arithmetic mean is appropriate for calculations of the cost of
22 capital.

1 While the geometric mean is the best estimate of actual performance over
2 a long period of time, this does not contradict the statement that the arithmetic mean,
3 compounded over the number of years for which an investment is held, provides the best
4 estimate of the ending wealth value of the investment. The reason is that an investment
5 with uncertain returns will have a higher ending wealth value than an investment that
6 simply earns (with certainty) its compound or geometric rate of return every year. In
7 other words, more money, or terminal wealth, is gained by the occurrence of higher than
8 expected returns than is lost by lower than expected returns.

9 In capital markets, where returns are a probability distribution, the answer
10 that takes account of uncertainty, the arithmetic mean, is thus the correct one for
11 estimating discount rates and the cost of capital.

12 **Q. You noted that Mr. Bible relies on total returns rather than income**
13 **returns on the long-term government bonds. Is it appropriate to calculate the**
14 **market risk premium using the total return on long-term government bonds?**

15 A. No, it is not. As discussed above the reliance on total returns as opposed
16 to income returns serves to greatly downwards bias the estimated market risk premium.

17 **Q. Why should the market risk premium be calculated using income**
18 **returns rather than total returns?**

19 A. Total returns have three components: the income return, the capital
20 appreciation return, and the reinvestment return. The only component that is truly
21 riskless is the income return for which reason it is the right benchmark to measure risk
22 premia against. As I note in my text, Regulatory Finance,

23 the long-term government bond *income* (yield) returns are
24 subtracted. The reason for subtracting the bond *income* returns

1 instead of the total return is that the yield of the bond reflects the
2 market's expectations at the time of purchase. This is not the case
3 with total returns, which can be biased by unanticipated capital
4 losses due to adverse interest rate movements.²⁵
5

6 Similarly, Ibbotson Associates on page 56 states

7 The equity risk premium is calculated by subtracting the arithmetic
8 mean of the government bond income return from the arithmetic
9 mean of the stock market total return.²⁶
10

11 To conclude, when measuring the market risk premium with
12 historical data the correct measures rely upon the arithmetic mean and
13 government bond income returns.

14 **Q. What is the net effect of Mr. Bible's erroneous reliance on the**
15 **geometric mean and total returns on long-term government bonds?**

16 A. The net effect of Mr. Bible's reliance on the geometric mean and total
17 returns on long-term government bonds as opposed to the arithmetic mean and income
18 returns on long-term government bonds is to decrease his estimate of the required market
19 risk premium by up to 4.40% (440 basis points). This in turn decreases his CAPM cost
20 of equity estimate by up to 2.4% (240 basis points). The latter estimate is derived by
21 using Mr. Bible's assumed beta of 0.55 and multiplying it by 4.40%, the difference
22 between the 1991-2000 arithmetic mean computed using income returns and the
23 geometric mean using total returns reported by Mr. Bible.²⁷

24 **Q. Does this conclude your rebuttal testimony?**

25 A. Yes, it does.

²⁵ Regulatory Finance, p. 313 n. 6.

²⁶ Ibbotson Associates: Stocks, Bonds, Bills, and Inflation Valuation Edition 2001 Yearbook p. 56.

²⁷ The aforementioned Ibbotson Associates publication used by Mr. Bible reports on p. 65 that the Market Risk Premium for the period 1991-2000 was 11.6%, compared to Mr. Bible's 7.27%. See also Ms. McShane's Table 8.

AFFIDAVIT OF ROGER A. MORIN

STATE OF GEORGIA)

) ss

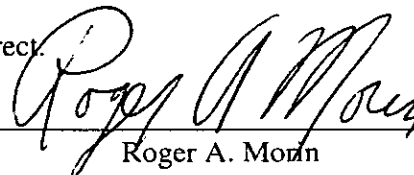

CITY OF ATLANTA)

Roger A. Morin, being first duly sworn on his oath, states:

1. My name is Roger A. Morin. I work in Atlanta, Georgia, and I am employed by Georgia State University.

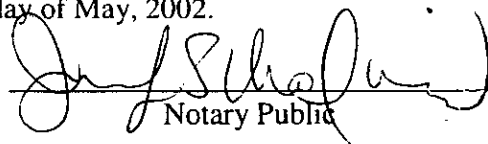

2. Attached hereto and made a part hereof for all purposes is my Rebuttal Testimony on behalf of Union Electric Company d/b/a AmerenUE consisting of 38 pages and Appendix A and Schedule 1, all of which have been prepared in written form for introduction into evidence in the above-referenced docket.

3. I hereby swear and affirm that my answers contained in the attached testimony to the questions therein propounded are true and correct.

Roger A. Morin

Subscribed and sworn to before me this 6th day of May, 2002.

Notary Public

My commission expires:

EXECUTIVE SUMMARY

Roger A. Morin

Professor of Finance at the College of Business, Georgia State University and Professor of Finance for Regulated Industry at the Center for the Study of Regulated Industry at Georgia State University; author of the widely-used treatise on regulatory finance, Utilities' Cost of Capital, and, more recently, Regulatory Finance.

* * * * *

1. Staff witness Ronald Bible has recommended a return on equity ("ROE") for AmerenUE in the range of 8.91% to 9.91%, with a midpoint of 9.41%. Mr. Bible's opinion as to an appropriate ROE for AmerenUE rests on his own unique approach that is not generally accepted, and indeed is far removed from the methodologies for estimating ROE that are reasonably relied upon by experts in the field. Mr. Bible's idiosyncratic approach does not originate from industry knowledge or any generally accepted approach and certainly has not been tested or subjected to peer review to determine its potential rate of error or its overall ability to provide this Commission with reliable information. At bottom, Mr. Bible's opinion as to an ROE for AmerenUE is so far outside the mainstream of financial theory and practice, is so fundamentally unsupported, and is, therefore, so unreliable, that it cannot be credited with providing the Commission any expert analysis that can assist it in responsibly addressing the important issues in this case.

My conclusion that Mr. Bible's approach is highly irregular and his recommendation flawed, grossly understating AmerenUE's cost of equity, is strikingly illustrated by the fact that his recommended 9.41% cost of equity lies well outside the zone of currently authorized rates of return for electric utilities in the United States

outside of Missouri, which, for AmerenUE's test year and update period, ranged from a low of 10.50% to a high of 12.90%. (This data is set out in Schedule 17 to the testimony of Kathleen McShane.) If adopted, Mr. Bible's draconian cost of equity recommendation of 9.41% would result in the lowest rate of return award for an electric utility in the country, and by a wide margin.

2. Mr. Bible has reduced and trivialized the process of determining cost of capital to a simple mechanical application of the DCF formula to Ameren alone, that is, to a one-company sample. In one obvious example of such trivialization, Mr. Bible ignores the results from his comparable group of three electric utilities and the results from other methodologies, notwithstanding the fact that these comparable companies currently have authorized returns on equity of 11.0%, 11.1%, and 11.7%. Mr. Bible does this in reliance on a "double" standard he simply creates, under which he will only question his DCF estimate if his results from other methods or results from comparable companies are "twice as much."

This "standard," which is purely Mr. Bible's and is not used by any reputable financial analysts or by others on the Commission's Staff, is so unreasonably broad as to make his Risk Premium and CAPM analyses wholly meaningless as checks on this DCF work, a consequence he freely admits. Moreover, this standard -- essentially a range of $\pm 9.41\%$ (or 941 basis points) around his DCF-based recommendation -- is utterly arbitrary, as can be seen by comparing it to the "reasonable range" he claims, also without justification, is appropriate for AmerenUE's cost of capital, which is only $\pm 0.5\%$ (or 50 basis points) around his midpoint.

3. As Mr. Bible admits, his “double” standard reduces his other results, which he purportedly uses to “check” his DCF result, to irrelevance. In truth then, Mr. Bible exclusively relies on a single DCF result, an approach wholly at odds with recognized standards for cost of capital analysis. His one-company DCF calculation is statistically invalid, violates the Central Limit Theorem, and violates the fundamental precepts of rate of return regulation embodied in the *Bluefield* and *Hope* landmark cases. Similarly, Mr. Bible's sample of only three comparable electric utilities to check his DCF estimate is statistically invalid, and, at bottom, produces highly unreliable results.

4. Mr. Bible relies inappropriately on electric utility historical growth data in his DCF analysis despite sea changes occurring in the industry that make the past a very uncertain basis by which to estimate the future growth rates needed for DCF calculations. Moreover, the historical growth rates that Mr. Bible uses in his DCF analysis are redundant (or double-count the past) since historical growth patterns are already taken into consideration in analysts' consensus growth forecasts, which he also uses. Compounding this fundamental flaw, Mr. Bible relies on historical data to do his calculations notwithstanding the fact that Ameren and two of the three comparable companies he selected have experienced recent mergers. As a result, data drawn from before these mergers is not comparable to data from after them, as the sources of this data expressly warn.

5. Mr. Bible employs historical and projected dividend growth in his DCF analysis even though, as he should know, electric utilities are reducing dividend payouts over the next several years in response to the gradual penetration of competition in the revenue stream and to the rising risk due to regulatory restructuring. As a result,

dividend growth numbers embody a downward prejudice, and can no longer accurately convey useful information about the future economic activity of a utility. Without a doubt, the use of historic or projected dividend growth (rather than earnings growth) is inappropriate in using the DCF model today, for they can only serve to artificially depress the results of the resulting estimate. Earnings growth projections are far more relevant.

6. Mr. Bible artificially creates a downward bias in his CAPM analyses by using historical beta estimates, because current changes in the risk fundamentals of the electric utility industry due to the introduction of competition, deregulation, and restructuring are not fully reflected in the historical betas on which he relies. Mr. Bible's estimate of the market risk premium, also for his CAPM work, erroneously relies in part on geometric averages of historical market returns (rather than on the correct arithmetic average) and on total returns on long-term government bonds (rather than income returns on long-term government bonds), which serves to substantially depress his estimate of the required market risk premium.

RESUME OF ROGER A. MORIN

(Spring 2002)

NAME: Roger A. Morin

ADDRESS: 10403 Big Canoe
Jasper, GA 30143, USA

E-MAIL ADDRESS: profmorin@msn.com

DATE OF BIRTH: 3/5/1945

PRESENT EMPLOYER: Georgia State University
Robinson College of Business
Atlanta, GA 30303

RANK: Professor of Finance

HONORS: Professor of Finance for Regulated Industry & Director
Center for the Study of Regulated Industry, College
of Business, Georgia State University.

EDUCATIONAL HISTORY

- Bachelor of Electrical Engineering, McGill University,
Montreal, Canada, 1967.
- Master of Business Administration, McGill University,
Montreal, Canada, 1969.
- PhD in Finance & Econometrics, Wharton School of Finance,
University of Pennsylvania, 1976.

EMPLOYMENT HISTORY

- Lecturer, Wharton School of Finance, Univ. of Pa., 1972-3
- Assistant Professor, University of Montreal School of Business, 1973-1976.
- Associate Professor, University of Montreal School of Business, 1976-1979.
- Professor of Finance, Georgia State University, 1979-2002
 - Professor of Finance for Regulated Industry and Director, Center for the Study of Regulated Industry, College of Business, Georgia State University, 1985-2002
- Visiting Professor of Finance, Amos Tuck School of Business, Dartmouth College, Hanover, N.H., 1986

OTHER BUSINESS ASSOCIATIONS

- Communications Engineer, Bell Canada, 1962-1967.
- Member of the Board of Directors, Financial Research Institute of Canada, 1974-1980.
- Co-founder and Director Canadian Finance Research Foundation, 1977.
- Vice-President of Research, Garmaise-Thomson & Associates, Investment Management Consultants, 1980-1981.
- Executive Visions Inc., Board of Directors, Member
- Board of External Advisors, College of Business, Georgia State University, Member 1987-1991
